Perinatal Asphyxia and Cerebral Palsy

Fact, Fiction, or Legal Prediction?

The scenario is familiar to all of us. A medical malpractice lawsuit has been filed on behalf of a child with cerebral palsy. An obstetrician and often the pediatrician who cared for the child at birth and many years hereafter receive court documents naming them as defendants in the suit.

See also p 1154.

The child may be several years old now and suffers from a visible and distressing physical condition. The plaintiff's attorney sorts through medical records with a fine-tooth comb looking for any potential impropriety, searching for fault in the mother's or child's medical treatment. The job of the plaintiff's attorney is to show that medical care rendered to the mother and/or infant fell "below accepted standards of care" and "to a medical probability" contributed to the child's

current medical condition.

The logic of this legal case often rests on the association of perinatal events to long-term neurologic sequelae such as cerebral palsy. However, there is an increasing body of medical knowledge bringing down the time-honored belief that catastrophic events surrounding the perinatal period lead to cerebral palsy. The work of Naeye et al,¹ published in this issue of *AJDC*, provides ongoing strong evidence that cerebral palsy is not the result of perinatal asphyxial events in the full-term infant, but the consequence of usually unpreventable prenatal intrauterine problems.

Cerebral palsy is a general descriptive term referring to a nonprogressive motor deficit of early onset. The specific type (spastic diplegic/quadruplegic, choreoathetoid, dystonic) is determined by the location of the lesions within the central nervous system and timing of its occurrence.²

When Little³ described this disorder in 1862, he was certain that the origins of the problems he found were related to the birthing process. Histories of prolonged labor, breech presentations, and premature birth were commonly found in children with "spastic rigidity." Many children presented with delayed onset of respirations, convulsions, and coma. However, a conflicting view was provided by Freud⁴ in his early career as a neurologist. In a monograph in 1897, he stated that

since the abnormal process of birth frequently produces no effect, one cannot exclude the possibility that, despite Little's anamnesis, diplegia still might be of congenital origin. Difficult birth in itself in certain cases is merely a symptom of deeper effects that influenced the development of the fetus.

For many years, it was believed that one of the complications of a breech birth was cerebral palsy. However, it

is now recognized that there is a higher incidence of abnormalities in fetuses found in a breech presentation.⁵ Abnormalities of labor and delivery may constitute markers rather than causes of brain damage. Thus, in many cases of cerebral palsy, it is probable that preexisting brain damage resulted in intrapartum neonatal asphyxia rather than the converse. Now, nearly 100 years later, we are at the forefront of realizing the truth and soundness of Freud's statement!

Utilizing data from the Collaborative Perinatal Study of the National Institute of Neurological and Communicative Disorders and Stroke, Bethesda, Md,⁶ Naeye et al sought to determine what role birth asphyxia plays in the development of cerebral palsy in full-term infants, and to ascertain whether disorders of intrauterine origin may manifest as cerebral palsy. The collaborative Perinatal Study followed the course of nearly 60 000 pregnancies in 12 medical school-affiliated hospitals from 1959 to 1966 in a careful prospective fashion. Although newer, precise methods of assessing favorability of the intrauterine environment (electronic fetal monitoring, pH sampling) were not in use then, indicators studied in the Collaborative Perinatal Study, such as neonatal seizures, time until the onset of respiration, and fetal bradycardia, are still valid indicators of a potentially hostile intrauterine environment. He found that birth asphyxia accounted for only 6% of the cases of cerebral palsy. Congenital disorders could be identified as a cause of cerebral palsy in many more cases of quadriplegic cerebral palsy than birth asphyxia. Naeye et al conclude that it is unlikely that state-of-the-art obstetric and pediatric managements could have prevented the cerebral palsy in these full-term infants since most of the disorders that damaged their brains occurred long before labor and delivery, and thus were unrecognized at the time the brain damage occurred.

Numerous studies have criticized the causal relationship of birth asphyxia and cerebral palsy on the presence of fetal distress and low Apgar scores.^{7,8} (I am sure that Dr Virginia Apgar never intended for her rapid,

numerical assessment of an infant's adaptation to extrauterine life to be used as a means for determining neurologic outcome!) To state that cerebral palsy was caused by birth asphyxia requires objective proof of a profoundly disturbed intrauterine environment, such as blood gas evidence of severe acidosis, hypoxia, and hypercarbia. In addition, there should be postnatal evidence of neurologic impairment (seizures, apnea, tone abnormalities) and other organ-system compromise, such as renal insufficiency and cardiovascular embarrassment. There must also be no evidence that a nonasphyxial condition was present that could have caused the cerebral palsy. Naeye et al¹ and Nelson and Ellenberg⁸ found that congenital malformations (hydrocephalus, microcephaly, etc) could explain many times more cases of cerebral palsy than did birth asphyxia. Yet, perhaps most important, is the discovery that no cause could be identified for the majority of cases of cerebral palsy in term infants. Nelson and Ellenberg concluded in their study of predictive factors of cerebral palsy that "we probably do not know what causes most cases of cerebral palsy." However, prematurity and low birth weight are strong risk factors for cerebral palsy.⁸ Prevention of preterm delivery would be a tremendous stride in preventing cerebral palsy.

What does all this mean for our obstetric colleagues? We must be prudent and exact in our medical documentation of infants with a complicated adaptation to extrauterine life. When an infant is born with Apgar scores of 2 and 5 at 1 and 5 minutes, respectively, we should not write in the chart an assessment of perinatal asphyxia (unless there is objective biochemical evidence to support this!). Perinatal asphyxia is a symptom complex indicative of an underlying pathophysiologic process. *Perinatal depression* may be a more appropriate descriptive term that does not point accusatory fingers at other health care providers. Few studies have shown that a poor neurodevelopmental outcome is the result of "substandard" obstetric care. As pointed out by Niswander et al,⁹ "fetal distress may oc-

casionally be followed by brain damage, but the obstetrician can seldom interrupt that relationship."

What is the role of the pediatrician in controlling the unchecked proliferation of obstetric malpractice suits? We must not ascribe apparent brain damage to intrapartum causes. We must carefully educate attorney (plaintiff and defense) and the public at-large that whenever there is a bad outcome, someone is not always to blame. We must dispel the plaintiff attorney's claim that intrapartum asphyxia causes brain damage. As more data are accumulated, the scientific verdict will be that perinatal asphyxia rarely leads to cerebral palsy or brain injury. The theory of perinatal acquisition of brain damage has a element of fiction and legal prediction. Preconceived ideas about the origin of cerebral palsy need stringent reassessment. Rather than nonscientific speculation on the origins of brain damage fanning the flames of the obstetric malpractice litigation fire, we should concentrate on "just the facts, ma'am, just the facts."

Leads From the MMWR

Morbidity and Mortality Report
Centers for Disease Control, Atlanta

Recommendations of the Immunization Practices Advisory Committee (ACIP) Mumps Prevention

THIS REVISED Immunization Practices Advisory Committee (ACIP) recommendation on mumps vaccine updates the 1982 recommendation.

MUMPS VIRUS VACCINE

Mumps virus vaccine is prepared in chick-embryo cell culture. The vaccine produces a subclinical, noncommunicable infection with very few side effects. Mumps vaccine is available both in monovalent (mumps only) form and in combinations: mumps-rubella and measles-mumps-rubella (MMR) vaccines.

The vaccine is approximately 95% efficacious in preventing mumps disease; greater than 97% of persons known to be susceptible to mumps develop measurable antibody following vaccination. Vaccine-induced antibody is protective and long-lasting, although of considerably lower titer than antibody resulting from natural infection. The duration of vaccine-induced immunity is unknown, but serologic and epidemiologic data collected during 20 years of live vaccine use indicate both the persistence of antibody and continuing protection against infection. Estimates of clinical vaccine efficacy ranging from 75% to 95% have been calculated from data collected in outbreak settings using different epidemiologic study designs.

Vaccine Shipment and Storage

Administration of improperly stored vaccine may fail to protect against mumps. During storage before reconstitution, mumps vaccine must be kept at 2-8 C (35.6-46.4 F) or colder. It must also be protected from light, which may inactivate the virus. Vaccine must be shipped at 10 C (50 F) or colder and may be shipped on dry ice.

After reconstitution, the vaccine should be stored in a dark place at 2-8 C (35.6-46.4 F) and discarded if not used within 8 hours.

VACCINE USAGE

General Recommendations

Susceptible children, adolescents, and adults should be vaccinated against mumps, unless vaccination is contraindicated. Mumps vaccine is of particular value for children approaching puberty and for adolescents and adults who have not had mumps. MMR vaccine is the vaccine of choice for routine administration. Persons should be considered susceptible to mumps unless they have documentation of (1) physician-diagnosed mumps, (2) adequate immunization with live mumps virus vaccine on or after their first birthday, or (3) laboratory evidence of immunity. Because live mumps vaccine was not used routinely before 1977 and because the peak age-specific incidence was in 5-9-year-olds before the vaccine was introduced, most persons born before 1957 are likely to have been infected naturally between 1957 and 1977. Therefore, they generally may be considered to be immune, even if they may not have had clinically recognizable mumps disease.

Persons who are unsure of their mumps disease history and/or mumps vaccination history should be vaccinated.

Age. Live mumps virus vaccine is recommended at any age on or after the first birthday for all susceptible persons, unless a contraindication exists.

Persons Exposed to Mumps

Use of Vaccine. When given after exposure to mumps, live mumps virus

vaccine may not provide protection.

Use of Immune Globulin. Immune globulin (IG) has not been demonstrated to be of established value in postexposure prophylaxis and is not recommended.

Adverse Effects of Vaccine Use

In field trials before licensure, illnesses did not occur more often in vaccinees than in unvaccinated controls. Reports of illnesses following mumps vaccination have mainly been episodes of parotitis and low-grade fever. Allergic reactions including rash, pruritus, and purpura have been temporally associated with mumps vaccination but are uncommon and usually mild and of brief duration.

Contraindications to Vaccine Use

Pregnancy. Although mumps vaccine virus has been shown to infect the placenta and fetus, there is no evidence that it causes congenital malformations in humans. However, because of the theoretical risk of fetal damage, it is prudent to avoid giving live virus vaccine to pregnant women.

Severe Febrile Illness. Vaccine administration should not be postponed because of minor or intercurrent febrile illnesses, such as mild upper respiratory infections.

Allergies. Because live mumps vaccine is produced in chick-embryo cell culture, persons with a history of anaphylactic reactions (hives, swelling of the mouth and throat, difficulty breathing, hypotension, or shock) after egg ingestion should be vaccinated only with caution using published protocols.

Since mumps vaccine contains trace amounts of neomycin (25 µg), persons who have experienced anaphylactic re-

actions to topically or systemically administered neomycin should not receive mumps vaccine.

Recent IG Injection. Passively acquired antibody can interfere with the response to live, attenuated-virus vaccines. Therefore, mumps vaccine should be given at least 2 weeks before the administration of IG or deferred until approximately 3 months after the administration of IG.

Altered Immunity. In theory, replication of the mumps vaccine virus may be potentiated in patients with immune deficiency diseases and by the suppressed immune responses that occur with leukemia, lymphoma, or generalized malignancy or with therapy with corticosteroids, alkylating drugs, antimetabolites, or radiation. In general, patients with such conditions should not be given live mumps virus vaccine. Because vaccinated persons do not transmit mumps vaccine virus, the risk of mumps exposure for those patients may be reduced by vaccinating their close susceptible contacts.

An exception to these general recommendations is in children infected with human immunodeficiency virus (HIV); all asymptomatic HIV-infected children should receive MMR at 15 months of age. If measles vaccine is administered to symptomatic HIV-infected children, the combination MMR vaccine is generally preferred.

Patients with leukemia in remission whose chemotherapy has been terminated for at least 3 months may also receive live mumps virus vaccine. Short-term (less than 2 weeks' duration) corticosteroid therapy, topical steroid therapy (e.g., nasal, skin), and intraarticular, bursal, or tendon injection with corticosteroids do not contraindicate mumps vaccine administration. However, mumps vaccine should be avoided if systemic immunosuppressive levels are reached by prolonged, extensive, topical application.

Other. There is no known association between mumps vaccination and pancreatic damage or subsequent development of diabetes mellitus.

MUMPS CONTROL

The principal strategy to prevent mumps is to achieve and maintain high immunization levels, primarily in infants and young children. Universal immunization as a part of good health care should be routinely carried out in physicians' offices and public health clinics. Programs aimed at vaccinating

children with MMR should be established and maintained in all communities. In addition, all other persons thought to be susceptible should be vaccinated unless otherwise contraindicated. This is especially important for adolescents and young adults in light of the recently observed increase in risk of disease in these populations.

Because access to some population subgroups is limited, the ACIP recommends taking maximal advantage of clinic visits to vaccinate susceptible persons greater than or equal to 15 months of age by administering MMR, diphtheria-tetanus-pertussis (DTP), and oral polio vaccine (OPV) simultaneously if all are needed. Health agencies should take necessary steps, including the development, adoption, and enforcement of comprehensive immunization requirements, to ensure that all persons in schools at all grade levels and in day-care settings are protected against mumps. Similar requirements should be considered for colleges, as recommended by the American College Health Association,²⁵ and selected places of employment where persons in this age cohort are likely to be concentrated or where the consequences of disease spread may be more severe (e.g., medical-care settings).

In determining means to control mumps outbreaks, exclusion of susceptible students from affected schools and schools judged by local public health authorities to be at risk for transmission should be considered. Such exclusion should be an effective means of terminating school outbreaks and quickly increasing rates of immunization. Excluded students can be readmitted immediately after vaccination. Pupils who have been exempted from mumps vaccination because of medical, religious, or other reasons should be excluded until at least 26 days after the onset of parotitis in the last person with mumps in the affected school. Experience with outbreak control for other vaccine-preventable diseases indicates that almost all students who are excluded from the outbreak area because they lack evidence of immunity quickly comply with requirements and can be readmitted to school.

MUMPS DISEASE SURVEILLANCE AND REPORTING OF ADVERSE EVENTS

There is a continuing need to improve the reporting of mumps cases

and complications and to document duration of vaccine effectiveness. Thus, for areas in which mumps reportable disease, all suspected cases of mumps should be reported to or state health officials.

The National Childhood Vaccine Injury Compensation Program established by the National Childhood Vaccine Injury Compensation Act of 1986 requires physicians and other health care providers who administer vaccines to maintain permanent immunization records and to report occurrences of certain adverse events to the U.S. Department of Health and Human Services. Reporting and reporting requirements took effect March 21, 1988. Reportable adverse events include those listed in the Code of Federal Regulations for mumps²⁶ and events specific to the manufacturer's vaccine package insert as contraindications to further doses of mumps vaccine.

Although there eventually will be one system for reporting adverse events following immunizations, separate systems currently exist. Appropriate reporting methods currently depend on the source of funding used to purchase the vaccine. Events that occur after receipt of vaccine purchased with public funds, federal, state, and/or local government funds must be reported by the administering health provider to the appropriate local, county, or state health department. The state health department completes and submits the report forms to CDC. Reportable events that follow administration of vaccine purchased with private money are reported by the health-care provider directly to the Food and Drug Administration.

RECOMMENDATIONS FOR INTERNATIONAL TRAVEL

Mumps is still endemic throughout most of the world. While vaccination against mumps is not a requirement for entry into any country, susceptible children, adolescents, and adults would benefit by being vaccinated with a single dose of vaccine (usually as MMR), unless contraindicated before beginning travel. Because of concern about inadequate seroconversion due to persisting maternal antibody and because the risk of serious disease from mumps infection is relatively low for persons less than 12 months of age, a vaccine need not be given mumps vaccine before travel. (*MMWR* vol 38, No.

When I was a child there was no Orimune®

Poliovirus Vaccine Live Oral Trivalent

Jackie DiLorenzo of Hastings-on-Hudson, New York, contracted polio in 1950, before a vaccine became available. She spent ten years in rehabilitation, during which time she underwent nine operations on her spine, legs and feet. Jackie currently lives in a house adapted for wheelchair living.

Lederle Biologicals Protecting Families Through Immunization®

Please see following page for brief summary of prescribing information.

about the award-winning
Adolescent Wellness Program

When I was a child there was no Orimune®

Proven in Millions of US Patients

ORIMUNE was the first live, oral, trivalent polio vaccine. No other oral polio vaccine has done more to help eradicate wild poliovirus in the US. Over 500 million doses have been distributed to date.

Proven Safety* Record

Lederle takes every precaution during production and testing to ensure the safety of ORIMUNE. This dedication is evident by our 27-year safety record.

Uninterrupted Supply

Lederle has consistently met the nation's needs for oral polio vaccine for about 27 years. In fact, when all other US manufacturers discontinued the production of oral polio vaccine, Lederle has remained committed to this essential product and to the health of America's children.

Available in Single-Doses

ORIMUNE is available in convenient, unit-dose DISPETTES® to help assure dosage accuracy and avoid the risk of contamination.

*Paralytic disease following ingestion of live poliovirus vaccine has been reported on rare occasions in individuals receiving the vaccine or in their close contacts.

Orimune®
Poliovirus Vaccine Live Oral Trivalent

Poliovirus Vaccine Live Oral Trivalent ORIMUNE®

A Brief Summary

Please see package insert for full description, directions for use, and references.

INDICATIONS: For prevention of poliomyelitis caused by Poliovirus Types 1, 2, and 3.

CONTRAINDICATIONS: Under no circumstances should this vaccine be administered parenterally.

Administration of the vaccine should be postponed or avoided in those experiencing any acute illness and in those with any advanced debilitated condition or persistent vomiting or diarrhea.

ORIMUNE must not be administered to patients with immune deficiency disease such as combined immunodeficiency, hypogammaglobulinemia, and agammaglobulinemia. Further, ORIMUNE must not be administered to patients with altered immune states, such as those occurring in thymic abnormalities, leukemia, lymphoma, or generalized malignancy or by lowered resistance from therapy with corticosteroids, alkylating drugs, antimetabolites, or radiation. ORIMUNE should not be given to members of a household in which there is a family history of immunodeficiency until the immune status of all members is determined to be normal. All persons with altered immune status should avoid close household-type contact with recipients of the vaccine for at least six to eight weeks. Inactivated poliovirus vaccine (IPV) is preferred for immunizing all persons in the above described circumstances.

WARNINGS: Under no circumstances should this vaccine be administered parenterally.

Administration of the vaccine should be postponed or avoided in those experiencing any acute illness and in those with any advanced debilitated condition or persistent vomiting or diarrhea.

Other viruses (including poliovirus and other enteroviruses) may interfere with the desired response to this vaccine, since their presence in the intestinal tract may interfere with the replication of the attenuated strains of poliovirus in the vaccine.

PRECAUTIONS: Preliminary data indicate that immune globulin (Human) (IG) does not appear to interfere with immunization with poliovirus vaccine live oral trivalent (OPV). However, until more data are available, it would seem prudent not to administer OPV shortly after IG, unless such a procedure is unavoidable, for example, with unexpected travel to or contact with epidemic areas or endemic areas. If OPV is given with or shortly after IG, the dose should probably be repeated after three months if immunization is still indicated.

The vaccine is not effective in modifying or preventing cases of existing and/or incubating poliomyelitis.

NATIONAL CHILDHOOD VACCINE INJURY ACT OF 1986 (as amended in 1987)

Manufacturer and lot number of vaccine administered must be recorded by health care provider in vaccine recipient's permanent record, along with date of administration and name, address, and title of person administering vaccine.

Health care provider must report to a health department or to the FDA the occurrence of any event set forth in the Vaccine Injury Table including: paralytic poliomyelitis—in a nonimmunodeficient recipient within 30 days of vaccination—in an immunodeficient recipient within 6 months of vaccination; any vaccine-associated community case of paralytic poliomyelitis; or any acute complication or sequela (including death) of above even if the vaccine is not used.

Use in Pregnancy: Pregnancy Category C: Animal reproduction studies have not been conducted with Poliovirus vaccine live oral trivalent. It is also not known whether OPV can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity.

Although there is no convincing evidence documenting adverse effects of either OPV or IPV on the developing fetus or pregnant woman, it is prudent on theoretical grounds to avoid vaccination of pregnant women. However, if immediate protection against poliomyelitis is needed, OPV is recommended. (See **CONTRAINDICATIONS** and **ADVERSE REACTIONS**.)

ADVERSE REACTIONS: Paralytic disease following the ingestion of live poliovirus vaccines has been, on rare occasion, reported in individuals receiving the vaccine (see, for example, **CONTRAINDICATIONS**), and in persons who were in close contact with vaccinees. The vaccine viruses are shed in the vaccinee's stools for at least six to eight weeks as well as via the pharyngeal route. Most reports of paralytic disease following ingestion of the vaccine or contact with a recent vaccinee are based on epidemiological analysis and temporal association between vaccination or contact and the onset of symptoms. Most authorities believe that a causal relationship exists. Prior to administration of the vaccine, the attending physician should warn or specifically direct personnel acting under his authority to convey the warning: the vaccinee, parent, guardian, or other responsible person of the possibility of vaccine-associated paralysis, particularly to susceptible family members and other close personal contacts.

The Centers for Disease Control report that during the years 1973 through 1984 approximately 274.1 million OPV doses were distributed in the US. During this period, 105 vaccine-associated cases were reported (1 case per 2.6 million doses distributed). Of these 105 cases, 35 occurred in vaccine recipients (1 case per 7.8 million doses distributed), 50 occurred in household and nonhousehold contacts of vaccinees (1 case per 5.5 million doses distributed), 14 occurred in immunodeficient recipients or contacts, and 6 occurred in persons with no history of vaccine exposure, from whom vaccine-like viruses were isolated.

Thirty-three (94%) of the recipient cases, 41 (82%) of the contact cases, and 5 (36%) of the immunodeficient cases were associated with the recipient's first dose of OPV. Because most cases of vaccine-associated paralysis have occurred in association with the first dose, the CDC has estimated the likelihood of paralysis in association with first v subsequent doses of OPV, using the number of births during 1973-1984 to estimate the number of first doses distributed, and subtracting this from the total distribution to estimate the number of subsequent doses distributed. This method estimates a frequency of paralysis for recipients of 1 case per 1.2 million first doses v 1 case per 116.5 million subsequent doses; for contacts one case per 1 million first doses v 25.9 million subsequent doses; with an overall frequency of 1 case per 520,000 first doses v 1 case per 12.3 million subsequent doses.

Other methods of estimating the likelihood of paralysis in association with OPV have been described. Because the number of susceptible vaccine recipients or contacts of recipients is not known, the true risk of vaccine-associated poliomyelitis is impossible to determine precisely.

When the attenuated vaccine strains are to be introduced into a household with adults who have not been adequately vaccinated or whose immune status cannot be determined, the risk of vaccine-associated paralysis can be reduced by giving the adults one dose of IPV per month for three months before the children receive Poliovirus vaccine live oral trivalent ORIMUNE. The children may receive the first dose of ORIMUNE at the same visit that the adult receives the third dose of IPV. The CDC reports that no paralytic reactions to IPV are known to have occurred since the 1955 cluster of poliomyelitis cases caused by vaccine that contained live polioviruses that had escaped inactivation.

The ACIP states: "Because of the overriding importance of ensuring prompt and complete immunization of the child and the extreme rarity of OPV-associated disease in contacts, the Committee recommends the administration of OPV to a child regardless of the poliovirus-vaccine status of adult household contacts. This is the usual practice in the United States. The responsible adult should be informed of the small risk involved. An acceptable alternative, if there is a strong assurance that ultimate, full immunization of the child will not be jeopardized or unduly delayed, is to immunize adults according to the schedule outlined above before g OPV to the child."

The ACIP has concluded that "Oral polio vaccine remains the vaccine of choice for primary immunization of children."

The Editorial Board Speaks . . .

William B. Strong, MD

Bill Strong has an enviable academic record. Entering the 1989-1990 academic year, he has published more than 200 articles, book chapters, and self-instructional materials. His research efforts have been strong, with more than \$2 million in extramural support. He has been most active in investigation of physical activity and nutrition in relation to cardiovascular disease. He has also been recognized locally, regionally, and nationally as an outstanding educator. Bill's service activities, apart from his editorship of the SPORTS MEDICINE section of *AJDC*, include chairmanship and membership on multiple national pediatric and cardiovascular committees. He has been on the faculty of the Medical College of Georgia, Augusta, for the past 20 years, and is currently professor of pediatrics and director of pediatric cardiology. Bill is married to Lynthia and they have six children, ranging in age from 19 to 28 years.

YOU ARE A PREVENTIVE CARDIOLOGIST: THE SCOPE OF PEDIATRIC PREVENTIVE CARDIOLOGY

The excitement of pediatric preventive cardiology arises from its magnitude. When one becomes involved in the practice of preventive cardiology, its relationship to general good health becomes self-evident. You have been trained as preventive cardiologists. Until now you have just not focused your activities on an organ system. Historically, pediatricians' natural bailiwick has been preventive medicine and public health. Pediatricians have always been interested in childhood nutrition; they have led the good fight against smoking and have encouraged children to be physically active. Prudent diet, physical activity, and nonsmoking are the pillars of the practice of preventive cardiology. The only difference between what pediatricians did and are beginning to do under the rubric of preventive cardiology is that they are now targeting their advocacy on an organ disease process.

The prevention or deferment of the symptomatic phase of chronic disease is dependent on the teaching and implementation of healthy life-styles early in life and reinforcing them at all appropriate encounters, ie, prenatally and during the first year of life, early childhood, late childhood, and adolescence. At each of these stages, messages for healthy behaviors should be provided to the child and parents. At each visit, the message should be appropriate to the age of the child and circumstance of the encounter. The approach to nonsmoking recommended by Perry and Silvis¹ is an excellent example of age- and encounter-specific guidelines.

Two major strategies in the prevention of adult-onset coronary artery disease and hypertension are available to the pediatrician: the high-risk approach and the community (population, public health) strategy. The high-risk approach identifies individuals at highest risk of future disease by some set of characteristics and targets these individuals for aggressive interventional strategies. Because of the phenomenon of tracking, this method of identification will affect the 5% to 10% at greatest risk for future disease. However, since one half the population is at risk for future disease, primary prevention also should be applied to the population as a whole. Because of the great prevalence of disease in the population,

the community approach believes that certain intervention should be recommended for the entire population, eg, prudent diet, nonsmoking, and regular physical activity. These are not very radical strategies. They encompass what most pediatricians recommend.

Most pediatric preventive cardiologists would support combination of community and high-risk strategies. The preventive pediatric cardiologist would suggest the community strategy plus an aggressive search for individuals at high risk because of their family history and/or elevated total cholesterol and low-density lipoproteins cholesterol levels.

Because only one half of youngsters with significantly elevated cholesterol levels (≥ 5.2 mmol/L) will have a positive family history, cholesterol screening of all children should be performed in the pediatrician's office.² The American Heart Foundation has presented a cogent argument for universal screening of all children prior to school entry. When serum cholesterol level is elevated, validation of the office test with lipoprotein profile will enable the pediatrician to identify children whose values are excessive.

Experience suggests that the young to middle-aged parent(s) of these children also will have elevated levels. The majority of these adults are unaware of their values. Approaching preventive cardiology as a family affair is crucial to compliance. What parents are not more likely to try to change their own life-styles when they are aware that it is in the best interest of their child?

Measurement of the child's cholesterol levels provides the pediatrician an excellent entrée into a discussion of the importance of good nutrition, the benefits of physical activity, and the importance of nonsmoking. Today parents want the child's pediatrician to be interested in good health and wellness. It is in everyone's best interest.

Natural History and Serologic Diagnosis of Infants Born to Human Immunodeficiency Virus–Infected Women

John P. Johnson, MD; Prasanna Nair, MD; Susan E. Hines, MS, CPNP; Sue W. Seiden, MS, CPNP; Lindsay Alger, MD; Daniel R. Revie; Kathleen M. O'Neil, MD; Richard Hebel, PhD

• Perinatal transmission of human immunodeficiency virus is thought to occur in 25% to 50% of the offspring of infected women. Standard diagnostic methods do not permit identification of the infected newborns. To assess diagnostic methods and document the natural history of perinatal human immunodeficiency virus infection, 20 children born to human immunodeficiency virus–infected women were followed prospectively for 18 months by measuring antibody titer, Western blot profiles, and antigenemia, and the results were compared with clinical outcome. Endogenous synthesis of anti-human immunodeficiency virus IgG was demonstrated in 6 of the 8 infected children. Four children synthesized IgM against human immunodeficiency virus. Five had demonstrable p24 antigenemia. No significant differences between infected and noninfected children were noted at birth except drug withdrawal, which occurred more frequently in noninfected infants. The incidence of adenopathy, hepatomegaly, and neurologic and immunologic abnormalities in the infected children were compared with noninfected children. The distinguishing illnesses were the opportunistic infections, lobar pneumonia, and failure to thrive. Seven of the 8 infected children had human immunodeficiency virus–mediated disease by 1 year of age (Centers for Disease Control [Atlanta, Ga] P2 classification), and four had acquired immunodeficiency syndrome (Centers for Disease Control P2D). These studies offer an approach to diagnosis of human immunodeficiency virus infection in infants and document the natural history and possible outcomes of infected children. (AJDC. 1989;143:1147-1153)

In 1983, the first evidence of acquired immunodeficiency syndrome (AIDS) in infants was presented.^{1,2} Since that time, the number of pediatric AIDS cases has grown rapidly to over 1300.³ There are many more children who have human immunodeficiency virus (HIV) infection with milder disease or no apparent disease.^{4,6} The Centers for Disease Control, Atlanta, Ga, have recommended the establishment of obstetric screening programs to prospectively identify infants with perinatal exposure to HIV.⁷ Appropriate counseling and health planning is complicated by uncertainties regarding diagnosis of HIV infection in infancy and the lack of prospective data regarding the natural history and outcome of HIV infection in infants.

For editorial comment see p 1138.

The major difficulty in diagnosis of HIV infection in infants results from placental transfer of maternal IgG to the fetal circulation, thereby preventing accurate diagnosis by routine enzyme-linked immunosorbent assay or Western blot. It has been estimated that 15 months are required before demonstration of antibody against HIV indicates infant infection.⁸ Recent evidence suggests that diagnosis in infants may be even more difficult because of delayed or absent synthesis of anti-HIV antibody in infected children.⁹⁻¹¹ Furthermore, no prospective assessment of other diagnostic methods (ie, IgM synthesis or antigen detection) for HIV infection are available.

It is uncertain what proportion of the infected pediatric population will develop AIDS or other HIV-mediated diseases, but this proportion is thought to be high.^{5,12} It has become clear that

there is a wide spectrum of presentations of HIV-mediated disease in children, including recurrent or unusual infections, neurologic disease, the wasting syndrome, and hematologic disorders.¹³⁻¹⁶

Lacking, however, is the detailed natural history data necessary for appropriate health maintenance, disease recognition, and early intervention. In this article, we present a prospective longitudinal study of the diagnostic, clinical, and laboratory findings in 20 children born to HIV-infected women. A variety of methods to document HIV infection have been studied. The age at onset of the signs and symptoms of HIV infection in infants is also documented. Evidence is presented that the majority of infected children (ie, 88%) will develop disease manifestations (Centers for Disease Control P2 classification) by 1 year of age—confirming the marked susceptibility of infants to HIV infection and the pressing need for interventional strategies.

PATIENTS AND METHODS Enrollment

All women presenting to the University of Maryland, Baltimore, obstetric service between September 1985 and March 1986 were screened for risk factors for HIV infection by written questionnaire. Women who identified a risk factor for HIV infection were then asked to participate in a study of AIDS risk for themselves and their children. Informed consent was obtained both for participation in the study and for HIV antibody testing in mother and child. All women who identified a risk factor for HIV infection agreed to participate in this study. Approximately 25% of these "at-risk" women were HIV seropositive. Ninety percent of the mothers were black with a mean age of 28.5 years, 80% were multiparous, and 50% continued to abuse drugs during pregnancy. None had AIDS.

*Number indicates month of age at first documentation of abnormalities. Some variation may be noted between age of onset and Centers for Disease Control (Atlanta, Ga) classification because of requirement for persistence and/or progression of abnormality. HIV indicates human immunodeficiency virus; Inc, increase.

Assessment

The offspring of the first 20 seropositive women were evaluated at birth, and at 2, 4, 6, 9, 12, and 18 months. Maternal risk factors were intravenous drug use (90%) and sexual partner of a drug user (10%). Children were assessed by two of three practitioners at each visit who had no knowledge of laboratory results of HIV diagnostic research procedures. Physical examination data were recorded on a precoded sheet for consistency in observation. None of the children were breast-fed and none received prophylactic medications. Physical findings were considered significant only if recorded at two separate visits. Adenopathy was defined as palpable nodes greater than 0.5 cm at two or more noncontiguous nonbilateral locations. Splenomegaly was diagnosed if the examiner could palpate a spleen tip below the left costal margin. Hepatomegaly was defined as a palpable liver more than 2 cm below the right costal margin. Hyperreflexia was diagnosed if reflexes were scored 3+ on a scale of 4+.

Blood was drawn at each visit. For serum studies, the blood was allowed to clot for 30 minutes at room temperature and centrifuged at 1500g for 10 minutes. The serum was frozen at -20°C and saved for later batch assay. T-cell subsets were analyzed using fresh heparinized blood by flow cytometry on a Coulter EPICS Profile (Coulter Electronics Co, Hialeah, Fla) using T-cell subset specific monoclonal antibodies purchased from Coulter. Total serum immunoglobulin values were determined by nephelometry (Beckman Instrument Corp, Palo Alto, Calif). Hypogammaglobulinemia and hypergammaglobulinemia were defined as values of less than or greater than 2 SDs from age-defined normal ranges, respectively.

Serologic Analysis

Antibody Titer.—Antibody titer against HIV was estimated using the DuPont

HTLV-III enzyme-linked immunosorbent assay according to the manufacturers' instructions (EI DuPont de Nemours, Wilmington, Del). The optical density from this assay is roughly proportional to the amount of anti-HIV antibody in the specimen according to the manufacturer.

Western Blot Analysis.—Western blotting for anti-HIV antibody was run using the kit developed by Biotech Research Laboratories, Rockville, Md, for EI DuPont de Nemours. Each sample was incubated overnight at room temperature with a nitrocellulose strip onto which sodium dodecylsulfate-separated HIV/H9 proteins had been electrotransferred. Twenty microliters (IgG detection) or 40 µL (IgM detection) of patient serum was diluted in 2 mL of blotting buffer containing TRIS-buffered saline solution, 5% goat serum, and 5% nonfat dry milk. Bound antibody was detected using biotinylated goat antihuman IgG (δ) or IgM (µ) followed by horseradish peroxidase-conjugated avidin. Bands were developed using diaminobenzidine. Reactive samples, appearing as brown bands, were compared with positive control sera. Samples were scored as positive by the criteria established by the Consortium for Retrovirology Serology Standardization.¹⁷ Samples were considered positive if bands were detected against p24 or p31 and gp41 or gp120/160. The presence of rheumatoid factor in the sera was ruled out using the Rheumatex assay (Wampole Diagnostics, Cranberry, NJ).

Antigen Assay.—Assay for viral antigen was performed using the kit developed by Abbott Laboratories (North Chicago, Ill) according to the manufacturers' instructions. This kit is primarily sensitive for detection of p24 antigen of HIV.

Statistical Analysis.—Data were analyzed using a two-tailed Student *t* test and a *z* test for comparison of rates of occurrence per child per year.¹⁸

RESULTS HIV Diagnosis

A diagnostic and clinical summary is presented in Table 1. Using a variety of methods, a total of 17 positive assays could be documented in 8 of the 20 children.

Anti-HIV antibody levels depicted in Fig 1 (top) show the relative anti-HIV antibody amount in the five children who demonstrated an increase during the first year of life. Figure 1 (bottom) demonstrates the patterns from three children who had decreasing anti-HIV antibody despite evidence of HIV infection. One child who had seronegative results from 6 months until 18 months of age seroconverted at 22 months of age, one child had HIV antigen in his serum, and one child synthesized IgM against HIV (see below).

Diagnosis by the acquisition of new bands on Western blot is demonstrated in Fig 2. Samples were collected at 2, 4, and 6 months of age from an infant who had met clinical criteria for AIDS by 4 months of age (patient 7). The acquisition of IgG antibody against p55, p51/66, and gp41 at 4 and 6 months of age confirms endogenous antibody synthesis and HIV infection in this child. Antibody against p17, p24, p31, and gp160 was persistently positive until this child's death at 7 months of age. Two of 20 children demonstrated new bands confirming HIV infection.

Four of the 20 children had evidence of anti-HIV IgM synthesis. Two children had IgM against HIV at birth; the other 2 children synthesized IgM

Fig 1.—Graph showing anti-human immunodeficiency virus antibody level. Serum collected at the indicated ages demonstrate increasing antibody levels (top) and decreasing antibody levels (bottom) in infants infected with human immunodeficiency virus. OD 405 indicates optical density at 405 nm.

Fig 2.—Western blot profile showing anti-human immunodeficiency virus IgG antibody. Sequential samples of serum were assayed in a child who developed clinical criteria for acquired immunodeficiency syndrome by 4 months of age. Note acquisition of bands against p55, p66, and gp41.

against HIV by 4 months of age. Of the 4 children with IgM-seropositive results, 3 subsequently developed anti-HIV antibodies of the IgG class (1 at 22 months of age). The other child lost anti-

body positivity (IgG and IgM) by 1 year of age but has slow growth and a low T4:T8 ratio, ie, less than 1.

Assay by antigen enzyme-linked immunosorbent assay revealed that 5 of 20

children had antigenemia by 4 months of age. Four of these children have gone on to develop clinical criteria for P2D classification by 1 year of age.⁸

In summary, a total of 17 positive assays could be documented in 8 of the 20 children by 6 months of age. Increasing antibody titer against HIV and antigen detection were equally sensitive, ie, positive in 5 children by 1 year of age. The IgM testing confirmed infection in 4 children and was the first positive test in 3. The acquisition of new IgG bands confirmed infection in 2 children. These 8 children, presumed to be infected, were compared with the 12 other children who served as controls for an assessment of the onset of disease processes presented below.

Natural History

There were no significant physical differences between the HIV-infected and the noninfected infants at birth (Table 2). Twenty-five percent (5/20) of the infants had birth weights below 2500 g; 2 of these infants later proved to be HIV infected. Similarly, 5 children were born before 35 weeks of gestation, 2 children in the infected group and 3 children in the noninfected group. One child in each group was small for gestational age. No child had dysmorphic features at birth, although by 9 months of age, 1 infected infant had mild dysmorphism consisting of hypertelorism, frontal bossing, and a flattened nasal bridge.¹⁹ Drug withdrawal symptoms were observed in 1 of the infected and 9 of the noninfected children ($P = .02$).

The prevalence of clinical abnormalities in infected children was compared with abnormalities in noninfected children by age of onset (Fig 3). Adenopathy was the most common abnormality observed in the HIV-infected children. This occurred in a significantly higher percentage of infected children (87%) than noninfected children (8.5%) by 4 months of age ($P < .001$). Splenomegaly tended to occur in children with adenopathy but was not reported in a statistically significantly greater proportion of infected children (62.5%) than found in the control population (25%; $P = .17$).

Hepatomegaly was observed in 5 of the infected children, compared with 1 of 12 noninfected children ($P = .02$). This tended to occur late in the first year

Table 2.—Perinatal and Neonatal Characteristics of Infants at Risk for HIV*

usually noted on the face and trunk and responded to topical treatment with hydrocortisone.

The Denver Developmental Screening Test was failed by 62.5% of the infected children and 25% of the noninfected children ($P = .17$). The incidence of language delay was not different in the two populations, occurring in four of the infected children and in three controls ($P = .36$). There was, however, a significant difference in the neurologic examination findings. Four of the infected children (50%) who had failed motor milestone assessments had hypertonicity and hyperreflexia. No abnormal upper motor neuron signs were reported in control children ($P = .01$).

Infections and Illnesses

Table 3 shows the frequency of infections in these children. Four of the infected children had infections meeting the diagnostic criteria for AIDS: two developed histologically proved *Pneumocystis carinii* pneumonia by 6 months of age. One of these children also had presumptive central nervous system toxoplasmosis. Two other children had recurrent serious bacterial infections, including sepsis and septic arthritis in one and recurrent sepsis and pneumonia in another.

The most frequent type of bacterial infection that distinguished the immunodeficient children from the control children was pneumonia. Five of the HIV-infected children had at least one episode of lobar pneumonia requiring antibiotic therapy. This occurred in 1 of the 12 noninfected children ($P = .02$). Two HIV-infected children had documented bacterial sepsis ($P = .15$). There was also a significantly greater incidence of failure to thrive occurring in 4 of the 8 infected children and none of the controls ($P = .01$). Two infected children had radiologic evidence of lymphoid interstitial pneumonitis during the study period ($P = .15$).

There was not a significant difference in the incidence of documented upper respiratory tract infections in the infected children. There also was not a significant difference in episodes of gastroenteritis in these children. On the other hand, unusual enteric pathogens were identified only in the infected children, including cryptosporidium in a

Fig 3.—Graph showing prevalence of clinical abnormalities. Percentage of children with the indicated clinical abnormality by age of development is shown for human immunodeficiency virus-infected (top) and noninfected (bottom) children.

of life. All of the infected children and two thirds of the noninfected children developed dermatitis. Candidial dermatitis accounted for the observed skin disease in half of the infected children and

in all of the noninfected children. The other skin abnormality, seen only in the infected children, was a generalized seborrheic rash that persisted in 3 children for several months. The rash was

Table 3. — Illnesses in Infants at Risk for HIV Infection in the First Years of Life*

child with *P. carinii* pneumonia, persistent adenovirus infection, and cytomegalovirus enteritis confirmed at autopsy.

Immunologic Studies

The most commonly observed laboratory abnormality in the children with HIV infection was hypergammaglobulinemia. This was observed in 50% of the infected children by 4 months of age and in 75% of the infected children by 9 months of age. None of the control children had hypergammaglobulinemia ($P < .001$). The next most frequent immunologic abnormality was an inverted T4:T8 ratio (< 1). This abnormality developed gradually and could be demonstrated in half of the infected children by 9 months of age. All but one infected child demonstrated an abnormal T4:T8 ratio by 18 months of age. Four children developed a frank deficit of T helper cells (< 800 cells/mm³). Lymphopenia was relatively uncommon in this population, occurring in only two of the most severely affected children late in the first year of life. No immunologic abnormalities were documented in the control children.

Classification

Six of the eight children developed HIV-mediated disease (Centers for Disease Control P2) by 6 months of age, as did a seventh child by 1 year of age. Four of these infected children developed AIDS and qualified for P2D class; the other three had milder signs and/or symptoms (P2A). One infected child re-

mained asymptomatic (P1A) during the study. She had been documented as HIV-infected by transient IgM seropositivity (2 and 4 months of age), which was unconfirmed until she developed IgG seropositivity at 22 months of age.

COMMENT

Conclusive diagnosis of congenital infection has always posed problems for pediatric practitioners. For many of the agents producing perinatal morbidity (ie, toxoplasmosis, cytomegalovirus, and rubella), recognizable clinical syndromes and diagnostic procedures have been established. Similar protocols are necessary to identify perinatal HIV transmission to infants.

We have been able to document infection in 8 of 20 infants at risk by 6 months of age using a battery of diagnostic techniques. This suggests a perinatal transmission rate of approximately 40% in this small population. This is similar to the rate observed in European studies of 34%²⁰ and 24%.²¹ One explanation for our somewhat higher transmission rate, other than the small population size, is that the European studies did not include either Western blot profile comparison or IgM testing in their assays for infection.

Serologic diagnosis of HIV infection is the standard in adults. Presence of anti-HIV IgG in an infant merely confirms the maternal infectious status. Longitudinal collection and batch assay by routine enzyme-linked immunosorbent assay for demonstration of increasing anti-HIV antibody titer identified

five (63%) of eight infected children by 1 year of life. A sixth child (patient 2) became seropositive at 22 months of age. Two infected infants have not demonstrated increasing anti-HIV IgG titer by enzyme-linked immunosorbent assay; one of these children was antigen-positive at birth and did demonstrate new band synthesis against HIV (patient 7). Therefore, seven (88%) of eight infected children in our study demonstrated an IgG response to HIV infection. The other infected, IgG seronegative, IgM seropositive child (patient 1) had physical findings and an inverted T4:T8 ratio consistent with HIV infection.

Two infants developed new antibody specificities against antigens of HIV not present at birth as demonstrated by Western blot.²² In one child, this approach permitted identification of endogenous IgG synthesis against HIV despite declining total anti-HIV antibody. Pyun et al²³ provided a conceptually similar approach by assessing the onset of IgG synthesis by analysis of antibody subclasses against HIV.

The disadvantage of procedures that assess the onset of IgG antibody synthesis against HIV is the time requirement for longitudinal study. Another disadvantage with extensive implications is that not all infected children will synthesize IgG against HIV in the first 18 months of life. Others have also demonstrated extended periods for seroconversion after perinatal infection, ie, up to 3 years.⁹⁻¹¹ It is clear that synthesis of IgG against HIV in infected infants may not occur and cannot be the sole basis for conclusive diagnosis.

Assay for IgM against HIV confirmed infection in four, ie, 50%, of the children. In a study of African children at risk for infection, IgM seropositivity was demonstrated in a similar proportion of infants at risk.²⁴ Two of the children who were IgM antibody-positive lost both IgM and IgG reactivity to HIV (patients 1 and 2). One child seroconverted at 22 months of age. The other child has subsequently exhibited negative results on in all assays (patient 1). It would appear, therefore, that although IgM detection will also not identify all infected infants, it may be the only serologic marker of infection in some children.

The antigen detection system identified 62.5% of the infected children. This is similar to viral detection in adults by this approach.²⁵ The children who had measurable serum antigen appear to have a poorer prognosis. Four of five antigen-positive children developed clinical criteria for P2D classification and AIDS by the ninth month of life. A similar relationship between antigenemia and disease development has been demonstrated in the adult population.²⁶

The performance of HIV culture in this population was not attempted. Such studies are currently under way, but the data in the adult population indicate that this will also have incomplete sensitivity for the detection of infection.²⁷ Furthermore, HIV culture methods are not sufficiently standardized to be of use in the general medical community.

Although estimates of specificity of these assays cannot be developed from this small population, it is clear that more sensitive and specific assays must be developed for confirmation of HIV infection in infants. Improved culture techniques or polymerase chain reaction techniques should enhance the currently available detection systems.^{28,29}

The lack of completely sensitive diagnostic criteria for HIV infection in the infant population has prompted the need for an awareness of the early clinical and laboratory signs suggestive of HIV infection. The manifestations of HIV infection in children have previously been well documented,¹²⁻¹⁷ but this prospective study yields some important comparisons.

The earliest and most common manifestation in HIV-infected children was the development of unusual lymphadenopathy. This was usually associated with hypergammaglobulinemia and frequently with splenomegaly. Skin diseases, and particularly candidal dermatitis, were common in both the infected and control children, although the infected children had more severe and persistent infections. A seborrheic rash was observed only in infected children and may be useful for identification. The cause of this rash is unclear but may relate to either an unidentifiable chronic infection or circulating immune complexes in these children.

Language delay in the at-risk, nonin-

fectured population is common and, therefore, not specific for HIV infection. On the other hand, signs of neurologic disease appear to be a specific finding, documented in half of the HIV-infected infants by 6 months of age. Several of the neurologically affected children had no evidence of associated immunodeficiency disease at the time, suggesting that infants with HIV infection are particularly susceptible to dementia.^{30,31}

Failure to thrive was seen only in the HIV-infected infants. A syndrome of failure to grow, failure to develop, dermatitis, and early death was seen in two of the eight infected children.

The most common laboratory abnormality was hypergammaglobulinemia. Hypogammaglobulinemia has been reported in a small proportion of children with AIDS, but was not observed in this population.⁵

The T-cell changes were relatively slow to evolve and tended to associate with, but appear later than, clinical immunodeficiency. We did not find other distinguishing hematologic abnormalities in these children although it has been reported that thrombocytopenia may be an initial presentation of HIV disease.³²

The unusual infections characteristic of AIDS readily indicate a child's HIV status. The development of opportunistic and/or recurrent bacterial infections before 1 year of age is well documented and underscores the marked susceptibility of the developing immune system to HIV. Somewhat surprising was the marked incidence of lower respiratory tract infections in the children with HIV infection during the first year of life. Presumed bacterial pneumonia was the most common infection in this population. Pneumonia is recognized as a frequent presentation of congenital immunodeficiency diseases and may be seen in children with either B-cell or T-cell abnormalities.

Only one infected child remained in the P1 category at 1 year of age. Infection in this child was documented by IgM seropositivity. Three of the four children who have not developed AIDS did synthesize anti-HIV IgM. It would appear from this limited population size that anti-HIV IgM may be associated with a better prognosis in HIV-infected children. Anti-HIV IgM detected post-

natally may indicate infection late pregnancy (or at delivery) and, therefore, may be associated with the appearance of signs and symptoms later in life. It is also possible that IgM may confer some protection to the child. Long-term follow-up will be necessary to determine the significance of these observations.

Most of the infected children had onset of HIV-mediated disease by months of age. Half of the infected children met the criteria for AIDS within the first year of life. Only one of eight children was asymptomatic by the end of the study. This supports the concept that infants may be particularly susceptible to the effects of HIV infection and raises concern over the large number of children born to women at risk for infection.

Also of concern is that four of the infected children had such mild symptoms (P1A or P2A) that they could go undiagnosed in a busy pediatric clinic. It is certain that there are many young children who have congenital HIV infection who have not developed marked degrees of immunodeficiency or neurologic disease. It is clear from these data that physical examination and readily available laboratory assessment will identify most HIV-infected children in the first year of life. Primary pediatric practitioners serving populations who may have risk factors must increase their awareness of possible perinatal HIV infection. Recognition and anticipation of the poor clinical outcome of HIV infection in children confirms the need to develop early, aggressive diagnosis and intervention to reduce the anticipated impact of perinatal HIV infection.

This work was funded in part by grant DAO43 from the National Institute of Drug Abuse, grant 90CA1318 from the Department of Health and Human Services, and by the Bressler Research Committee and the Medical Biotechnology Center of the University of Maryland at Baltimore.

We wish to acknowledge Sandra Barcroft for manuscript preparation.

Origins of Cerebral Palsy

Richard L. Naeye, MD; Ellen C. Peters; Mary Bartholomew, MS; J. Richard Landis, PhD

• Analyses were undertaken to determine the causes of cerebral palsy in a prospective study of 43 437 full-term children. Presumed causes were found for about 71% of the 34 quadriplegic and 40% of the 116 nonquadriplegic patients with cerebral palsy. Risk estimates based on predictive models, adjusted for multiple factors, suggest that 53% of the quadriplegic patients with cerebral palsy could be attributed to congenital disorders, 14% to birth asphyxia, and 8% to other identified disorders. Thirty-five percent of the nonquadriplegic patients with cerebral palsy could be attributed to congenital disorders and 6% to other disorders. In the victims of cerebral palsy, characteristic consequences of birth asphyxia were more often the result of nonasphyxial disorders. These included meconium in the amniotic fluid, low 10-minute Apgar scores, neonatal apnea spells, seizures, persisting neurologic abnormalities, and slow head growth after birth.

(AJDC. 1989;143:1154-1161)

This study was undertaken to try to identify and quantitate the major causes of cerebral palsy (CP). The analyses were based on specific disorders that might damage a child's brain. The most widely discussed of these disorders is birth asphyxia, with some people claiming that it is a frequent and others

For editorial comment see p 1139.

that it is a rare cause of CP. In recent years, the latter view has gained credence because very few victims of CP have had an asphyxial disorder recognized at birth.¹⁻¹⁰ This failure to recognize asphyxial disorders in victims of CP

could be misleading, because it is possible that such disorders are being missed or that insufficient cases have been analyzed to find a correlation between them and CP. The first goal of the present study was to determine how much of a role birth asphyxia has in the genesis of CP. A second goal was to quantitate the roles of chronic antenatal hypoxia disorders, congenital disorders, infections, trauma, hypoglycemia, oxytocin, and other prenatal and postnatal factors as causes of CP.

Most studies that have attempted to determine if birth asphyxia is a cause of CP have used low Apgar scores and fetal distress to identify asphyxia.^{1,10-19} Low Apgar scores and fetal distress are often nonhypoxic in origin, so their use as indicators of birth asphyxia could misattribute some nonasphyxial CP to asphyxia.^{2,20,21} We explored this possibility by seeing how many victims of CP who had low Apgar scores had a nonasphyxial disorder as the basis for their CP.

The final goal of the present study was to determine if some of the major causes of CP produce clinical findings that are distinctive enough to make their use a valid method for identifying the cause of CP in individual victims of CP. We particularly wanted to see if the neonatal manifestations of asphyxia-caused CP overlap the neonatal manifestations of CP caused by other disorders. For example, neonatal apneic spells, newborn neurologic abnormalities, and early neonatal seizures are well-known consequences of birth asphyxia.^{1,11,13,22} Is their presence proof that CP had an asphyxial origin or are they sometimes manifestations of CP caused by other disorders? We looked for an answer to this question.

METHODS

Data from the Collaborative Perinatal Study (CPS) of the National Institute of Neu-

rological and Communicative Disorders and Stroke, Bethesda, Md, were utilized in this investigation.²³⁻²⁷ The CPS was undertaken to identify fetal, intrapartum, and neonatal events that affect children's development. Its major aim was to determine if there are preventable causes of CP and other neurologic disorders. Cerebral palsy was defined as a chronic disability due to abnormal control of movements or posture that appears early in life and was nonprogressive. The CPS prospectively followed the course of the pregnancies of 58 947 women in 12 medical school-affiliated hospitals in different regions of the United States between 1959 and 1966. Events of gestation, labor, delivery, and the neonatal periods were recorded, as well as children's psychomotor, sensory, and physical development to 7 years of age. Detailed descriptions of the sampling methods, definitions, and study procedures have been published.^{16,23-29} The last neurologic examination in the study was conducted in 1973, at which time all the data became available for analysis on computer tapes in 1976. These data are still being analyzed today, because they comprise the largest and most complete set of prospectively collected information ever gathered to study the genesis of CP.

The current study focuses on two groups of full-term CPS children, 127 who had CP diagnosed by neurologic examination at 7 years of age and 23 who had CP diagnosed at 1 year of age and then died before reaching 7 years of age. The 150 children in these two groups include all CP cases, from mild to severe, in a subset of 43 437 full-term CPS children. *Full-term* was defined as birth at or after 37 weeks of gestation. Thirty-four of the 150 children had quadriplegic and 116 had nonquadriplegic CP. The children with quadriplegic CP were those who had abnormalities in the control of all four extremities. Children with hemiplegic, diplegic, and paraplegic CP were included in the nonquadriplegic category. Of the original 58 957 children in the CPS, 2865 could not be analyzed because their mothers delivered at a non-CPS hospital. Another 12 655 children were not included in the current analyses because they were born before term or lacked follow-up information. Most of those who lacked follow-up information had moved away from the CPS study center where they were born before the

Table 1.—Disorders Included in Two Composite Categories*

Birth asphyxial factors (47 children were exposed to one or more of the following antenatal disorders and had seizures in the neonatal period)†
Abruptio placentae (n = 2)
Tight knot in umbilical cord (n = 1)
Active labor lasted >20 h (n = 10)
Tumultuous labor (n = 1)
Maternal shock (n = 4)
Severe fetal hemorrhage (n = 3)
Umbilical cord tight around neck or body (n = 11)
Umbilical cord prolapse (n = 4)
Arrested progress of active labor (n = 8)
Persistent high uterine tone during labor (n = 3)
Maternal anesthesia accident (n = 4)
Severe vaginal bleeding at delivery (n = 11)
Chronic antenatal hypoxic disorders (16 689 children were exposed to one or more of the following antenatal disorders)
Maternal anemia (third trimester hemoglobin level <90 g/L (n = 3059)
Midpregnancy maternal hemoglobin value \geq 125 g/L (low first trimester blood volume expansion) (n = 5740)
Disorders that produce low uteroplacental blood flow
Preeclampsia and chronic gestational hypertension (n = 2164)
Unexpected drop in third trimester maternal blood pressure (n = 3985)
Postterm delivery (n = 2968)
Multiple births (n = 537)

*There were 43 437 full-term children in the study as a whole. Brain damage due to any of the above disorders could have been the result of ischemia, as well as the consequence of asphyxia or hypoxia.

†Neonatal seizures also had to be present for a case to be included in the birth asphyxia category.

Table 2.—The Rate of Clinical Findings per 1000 Births With Birth Asphyxia and Congenital Disorder Subgroups

Clinical Findings	Rate/1000 Births (No. of Children)				Total No. of Children
	Birth Asphyxia		Congenital Disorders		
	Absent	Present	Absent	Present	
Meconium in amniotic fluid	198 (8624)	200 (6)	194 (7633)	241 (997)*	8630
Apgar scores at 1 and 10 min 0-3 and 0-5	6 (253)	383 (18)	5 (206)	16 (65)*	271
0-3 and 6-10	39 (1681)	213 (10)*	37 (1454)	57 (237)*	1691
Neonatal hypotonia	13 (554)	702 (33)*	10 (377)	51 (210)*	587
Neonatal seizures	3 (155)	...	2 (82)	18 (73)*	155
Neonatal apneic episodes	3 (118)	340 (16)*	2 (75)	14 (59)*	134
Neurologic abnormalities in neonatal period	95 (4121)	1000 (47)*	81 (3186)	238 (982)*	4167
Neurologic abnormalities develop during first year of life	57 (2450)	0	54 (2114)	81 (336)*	2450
Head circumference 1st to 10th percentiles at birth	59 (2539)	149 (7)*	57 (2233)	76 (313)*	2546
Head circumference increase <10 cm in first year of life	38 (1639)	455 (11)*	37 (1455)	47 (195)*	1650
Total No. of children in the category	43 390	47	39 313	4124	43 437

* $P < .005$ for rate between clinical finding present and absent within a subgroup.

reached 7 years of age. Preterm children, those born before 38 weeks of gestation, were not included in the current study, because the clinical management of preterm children has changed too much since the CPS data were collected to be sure that the CPS findings on such children are valid for children born before term today.

The following approach was used to try to determine if birth asphyxial disorders are commonly being missed in studies of the ori-

gins of CP. Birth asphyxia severe enough to damage the brain causes characteristic clinical findings in the neonate including low 10-minute Apgar scores, seizures, apnea spells, hypotonia, and other neurologic abnormalities (Tables 1 and 2).^{1,11-18} If analyses found that all cases of CP that follow one or more of these clinical findings were explained by specifically identified brain-damaging disorders, the possibility would be increased that the analyses were recognizing all of the cases

of asphyxia-initiated CP.

Another strategy was employed to try to insure that enough children were being analyzed to accurately assess the role of birth asphyxia in CP. Both CP and individual birth asphyxial disorders have low frequencies in the general population, so if birth asphyxia is responsible for only a few percent of CP cases, a larger study than has been undertaken to date might be needed to determine whether a correlation exists between individual asphyxial disorders and CP. To try to overcome this problem, we consolidated all of the disorders that can cause birth asphyxia in the current study into a single composite category, which we termed *birth asphyxial factors* (Tables 1 and 3). By this method, enough birth-asphyxiated children should be present to quantitatively assess the role of birth asphyxia in CP. To insure that children placed in the birth asphyxia category experienced enough asphyxia or hypoxia to affect their brains, they also had to have had one or more seizures in the neonatal period. The CP that follows birth asphyxia is usually the result of cerebral ischemia or vascular occlusions that lead to necrosis and cerebral edema, which in turn almost always produce seizures in the neonatal period.^{13,18,30-32} Using these criteria, 47 children who were alive at 1 week of age were classified as having experienced birth asphyxia (Tables 1 and 3).

The criteria to be placed in a composite category labeled *chronic antenatal hypoxia disorders* (Tables 1 and 3) were met by 16 689 children. Disorders and conditions that can cause antenatal hypoxia or ischemia for several days or longer were classified as chronic antenatal hypoxia disorders. Such hypoxia is most often the result of chronic low blood flow from the uterus to the placenta, maternal anemia, or a continuation of pregnancy beyond 42 weeks of gestation (postterm).^{24,33} The most frequent causes of low uteroplacental blood flow are subnormal maternal blood volume expansion during the first trimester of pregnancy, preeclampsia, unexpected third trimester drops in maternal blood pressure, and multiple fetuses.^{24,34-38} In a normal pregnancy, maternal blood volume expands by about 50% between the 8th and the 14th weeks of gestation.³⁵ More of this blood volume increase is due to plasma volume expansion than to erythrocyte increase, so hemodilution normally reduces hemoglobin levels and hematocrit values before midgestation. In the present study, mid-second trimester hemoglobin levels equal to or greater than 125 g/L were used as an indication that blood volume increase may have been subnormal. We would have used a higher hemoglobin level to identify gravidas with possible low blood volume expansion if the women in the CPS had routinely received supplemental iron during pregnancy. They did not rou-

Table 3.—Frequency Distribution of Cerebral Palsy Status by Composite and Individual Risk Factors

Variable	No. (%) of Children			Total

*P<.01 compared with all cases in study.

tinely receive such iron. A gravida was identified as preeclamptic when she had two or more gestational diastolic blood pressures equal to or greater than 86 mm Hg accompanied by 1+ or greater proteinuria. An unexpected third trimester blood pressure drop was diagnosed when diastolic blood pressure decreased 20 mm Hg or more between third trimester clinic visits to a value of 60 mm Hg or less. A preliminary analysis found that such blood pressure drops were followed by a greater-than-expected frequency of long-term neurologic abnormalities.³⁸ Multiple births were placed in the chronic antenatal hypoxia category, because uteroplacental blood flow is usually low for individual fetuses when two or more fetuses are present.³⁷

The problem of limited sample size could have prevented previous studies from identifying some nonasphyxial causes of CP, so we put nonasphyxial disorders that have common mechanisms of action into single composite categories for the current analyses (Table 3). Examinations during the first year of life were the basis for diagnosing congenital malformations. One composite group contained children who had major central nervous system (CNS) malformations. Another composite group contained children who had major non-CNS malformations. A third composite category included children who had

minor congenital malformations. Major malformations were those that might shorten life span; and minor malformations, those that did not pose such a threat. A fourth category included children who had congenital syndromes. This congenital syndrome category contained children who had recognized combinations of phenotypic findings that have been given names and have a congenital origin. The composite category motor disorders in siblings contained children who had one or more siblings with a chronic motor disorder. The composite category, birth trauma, included children with skull fractures, children on whom high forceps had been used, and cases in which the progress of active labor had been arrested for greater than 10 hours.

Conditions that can cause severe fetal or neonatal hypoglycemia were combined into a composite category labeled *fetal/neonatal hypoglycemia*. It included children who had symptomatic hypoglycemia during the neonatal period and children whose diabetic mothers had one or more episodes of severe hypoglycemia during pregnancy.²⁷ Two composite categories of postneonatal disorders were also analyzed: symptomatic intoxications and CNS infections. Symptomatic intoxications were the result of accidental ingestions of drugs and chemicals. The most frequent of the drugs and chemicals were kerosene, gasoline, salicylates, and lead.

Central nervous system infections include encephalitis and meningitis that develop between birth and 1 year of age.

Other possible risk factors for CP were analyzed individually rather than in composite categories (Table 3). Among these risk factors, unexplained gestational proteinuria describes gravidas who had 2+ or greater proteinuria that was unexplained by hypertension or urinary tract infections. There were 643 gravidas in this category. Previous analyses of the CPS data found that such proteinuria was followed by a greater-than-expected frequency of long-term neurologic abnormalities.³⁸ Other maternal pregnancy factors that were analyzed individually for their relationship to CP were cigarette smoking, total maternal pregnancy weight gain, and diabetes mellitus.²⁴ Forty-eight percent of the women smoked during pregnancy and 1.6% had pregravid or gestational diabetes mellitus. Data on cigarette smoking were collected at each clinic visit throughout pregnancy and analyzed by the average number of cigarettes smoked per day.²³⁻²⁷ Addiction to illicit drugs was not included as a risk factor in the analyses, because no detailed information was collected on the drugs used, their amounts, or the timing of their use.

Delivery factors that were analyzed individually for their relationship to CP were the use of oxytocin to start or to potentiate labor, breech delivery, and the use of gas anesthesia (Table 3).^{24,27} Oxytocin was not included in the composite birth asphyxia category, because it was administered so frequently (67% CPS gravidas) that it could be individualized as a risk factor.

Neonatal factors that were individually analyzed were the sex of the child, the presence of the respiratory distress syndrome (in children), and hyperbilirubinemia (448 children). Hyperbilirubinemia was diagnosed when neonatal serum bilirubin level reached or exceeded 307 $\mu\text{mol/L}$.

The results of a nonverbal intelligence test (Science Research Associates test) given to each gravida was analyzed for its relationship to CP.²⁷ Noneclamptic maternal seizure disorders were also analyzed as a separate risk factor for CP. Such seizures had a somewhat higher frequency in the CPS women than in women in the general population (Table 3). Demographic factors that were analyzed individually included race (46% white, 46% black, 8% other), years of maternal education, family income, and the type of employment of the head of household.²⁷

Studies were also undertaken to see if clinical findings, particularly those in the neonatal period, could be used to help identify the causes of CP. We particularly wanted to know if birth asphyxia produced a pattern of clinical findings that was distinctive enough to distinguish asphyxia-initiated CP from CP

Table 4.—Rate per 1000 Births, Relative Risk, Attributable Risk, and 95% Confidence Intervals for Risk of Quadriplegic Cerebral Palsy (CP) by Risk Factors

of other origins (Table 2). The clinical findings analyzed were meconium in the amniotic fluid, low 1-minute and 10-minute Apgar scores, neonatal seizures, multiple episodes of neonatal apnea, small head circumference at birth (1st to 10th percentiles),³⁹ slow head circumference growth during the first year of life (<10 cm), and the child's age at which neurologic abnormalities first appeared (neonatal, in the first year of life, between 1 and 2 years of age).

Multiple logistic regression was the method used to identify risk factors that were significantly associated with CP.⁴⁰ Factors not significantly associated with CP in these analyses are not reported in the tables of this study, with the exception of disorders and factors that are sometimes claimed to be a cause of CP (Table 3). A method for estimat-

ing population attributable risk from these logistic regression models described by Bruzzi et al⁴¹ was utilized to estimate the relative contribution of each factor when adjusted for all of the other risk factors in the model. The recently developed methods of Benichou and Gail⁴² were employed to construct 95% confidence intervals for the relative risk and attributable risk estimates (Tables 4 through 6). For example, an attributable risk of 0.53 from model No. 2 in Table 4 indicates that 53% of the CP cases are estimated to be attributable to one or more congenital disorders, given adjustments for birth asphyxia and CNS infections. Up to four risk factors were included in each analysis for relative risk and attributable risk. Any risk factor with a pair-wise correlation coefficient of at least .04 with another risk

factor was incorporated into the same four-factor risk model, so that conditional risks could be estimated for each key factor.

RESULTS

There were 150 cases of CP in the present study (0.34%), a rate of 1 in 290 full-term children (Table 3). Only 9 (6%) of the 150 victims of CP had birth asphyxia as the presumed cause of their CP. Six of the 9 had quadriplegic and 3 had nonquadriplegic CP. There was no significant association of CP with chronic antenatal hypoxic disorders (Table 3). Based on attributable risk estimates, congenital disorders explained over half (53%) of the cases of quadriplegic CP in the study (Table 4). Fourteen percent of the cases of quadriplegic CP was attributable to birth asphyxia and 8% to CNS infections. Congenital disorders explained about one third and CNS infections about 1 of 20 of the cases of nonquadriplegic CP (Table 5). No cause could be identified for nearly 60% of the nonquadriplegic patients with CP. Birth asphyxia was not a significant antecedent of nonquadriplegic CP (Table 5).

Another perspective is gained by looking at the relative risks of the various risk factors for CP. Birth asphyxia had the highest relative risk for quadriplegic CP, 52.5 (Table 4). However, the low frequency of birth asphyxia in the population as a whole (47 of 43 437) gave birth asphyxia a much smaller role as a cause of quadriplegic CP (attributable risk, 0.14) than the 52.5 relative risk value might suggest. Central nervous system infections and a variety of congenital disorders had high relative risks for both quadriplegic and nonquadriplegic CP (Tables 4 and 5). The CNS malformations that were most often associated with CP were hydrocephalus (8 cases), meningomyelocele (5 cases), and encephalocele (3 cases). Cardiac malformations (18 cases) were the most frequent non-CNS malformations among the victims of CP. Neonatal seizures were 35% ($P<.01$) more frequent after oxytocin was administered than when it was not used, but there was no corresponding increase in the frequency of CP after oxytocin use (Table 3). Fetal/neonatal hypoglycemia and the use of gas anesthesia at delivery were not associated with greater-than-expected frequencies of CP (Table 3).

Low 10-minute Apgar scores, neona-

tal hypotonia, neonatal apneic spells, neonatal neurologic abnormalities, and slow head growth after birth are all well-known consequences of birth asphyxia that is severe enough to damage the CNS. In the present study, these clinical findings were more often associated with congenital disorders than with birth asphyxia (Tables 2 and 6). The same was true for neonatal seizures (Table 6). Apgar scores that were low at 1 minute and recovered to a normal or near-normal value by 10 minutes were present in only two children with CP who were in the birth asphyxia category, but they were present in six victims of CP whose CP had a congenital origin (Table 6).

Children exposed to birth asphyxial disorders had a very high frequency of intrapartum and neonatal deaths. One hundred sixty-nine (43%) of the 397 children who were stillborn, and 447 (47%) of the 952 children who died in the first week of life had been exposed to a specifically identified birth asphyxial disorder. Of the 47 children in the birth asphyxial category who were still alive at 1 week of age, 15 (32%) died during the first month of life and another 8 (17%) died before 7 years of age. Of the 24 who were alive at 7 years, 6 (25%) had quadriplegic CP; 3 (13%), non-quadruplegic CP; and 2 (8%), other chronic neurologic abnormalities.

COMMENT

Birth asphyxia accounted for 6% (9/150) of the CP cases in the study as a whole. This included 6 of 34 cases of quadriplegic and 3 of 116 cases of non-quadruplegic CP. No cases of CP due to birth asphyxia were likely missed in the analyses, because every child in the birth asphyxia category had neonatal neurologic abnormalities, and all 49 victims of CP in the study who had neonatal neurologic abnormalities had an explanation for their CP: 9 had birth asphyxia; 36, congenital disorders; and 4, CNS infections.

Congenital disorders explained nearly four times as many cases of quadriplegic CP than did birth asphyxia (attributable risks, 53% vs 14%, respectively). Congenital disorders were the only factor that explained a large number of the nonquadruplegic CP cases. It is also noteworthy that oxytocin, whose use

*Minor congenital malformations were not included in these analyses. Number of victims of CP are in parentheses in second column. CNS indicates central nervous system.

was followed by an increased frequency of neonatal seizures, was not followed by a corresponding increase in the frequency of CP. Gas anesthesia, maternal seizures, maternal diabetes mellitus, and fetal/neonatal hypoglycemia were also not associated with a greater-than-expected frequency of CP.

Many previous studies have based their identification of asphyxia-originated CP on the presence of fetal distress and low Apgar scores.^{1,10-19} In the present study, low 10-minute Apgar scores were more often associated with congenital disorders than with birth asphyxia in victims of CP. Other clinical findings that characteristically follow birth asphyxia were also more often related to congenital disorders than to birth asphyxia in the children with CP. These findings include meconium in the amniotic fluid, neonatal seizures, neonatal apnea spells, neurologic abnormalities in the neonatal period, and slow head growth after birth. Therefore, these clinical findings, by themselves, cannot be trusted to distinguish CP of asphyxial origin from CP due to other causes. To establish that a child's CP was caused by birth asphyxia, a specific

asphyxial disorder needs to have been identified, gas and pH evidences of asphyxia must have been present in fetal blood, neurologic abnormalities should have persisted throughout the newborn period, and there should be no evidence of a nonasphyxial disorder that could have caused the CP. By itself, the finding of acidosis in fetal blood is not proof that birth asphyxia caused CP. Almost no correlation has been found between such acidosis and the presence of neurologic abnormalities in the neonatal period.⁴³⁻⁴⁵ The duration of bearing down during labor has a strong positive correlation with fetal acidosis, and it may be that the duration of bearing down is usually too short to produce even transient asphyxial brain damage.³⁶

No cause could be identified for 60% of the nonquadriplegic CP cases in the study. Birth asphyxia was not a significant risk for nonquadriplegic CP in the attributable risk analysis, and as previously mentioned, birth asphyxial disorders were not likely missed in the children with CP. Twenty-eight percent of the children who eventually developed nonquadriplegic CP had their neurologic abnormalities first recognized be-

tween 1 and 2 years of age. This long delay in the first appearance of neurologic abnormalities presumably reflects brain injury or maldevelopment that was less severe than that present in the children who developed quadriplegic CP. Seventeen of the 116 children with nonquadriplegic CP had recognized CNS malformations. This could be an underestimate of such malformations in the nonquadriplegic victims of CP, because the diagnostic tools available in the CPS missed many CNS malformations that could be identified by diagnostic tools that are in use today.

All the evidence that birth asphyxia caused only 6% of the CP cases in the current study might seem inconsistent with the frequent findings at autopsy of acute asphyxial lesions in the brains of children who were stillborn or who died in the newborn period as the result of birth asphyxial disorders. There is a simple explanation for the high frequency of these asphyxial lesions. Birth asphyxia or hypoxia that is severe enough to damage the fetal brain usually kills before or soon after birth.^{1,17,48} This is what apparently happened in the present study. Almost half of the 1349 children who were stillborn or died in the neonatal period died as the direct or indirect result of birth asphyxial disorders. Only 24 of the children in the birth asphyxial category survived to 7 years of age, and 11 of the 24 had CP or other neurologic abnormalities. The margin between the level at which intrapartum hypoxia begins to damage the fetal brain and the level at which it kills is very narrow.^{1,47} The ability of Myers and his associates⁴⁹⁻⁵² to produce severe brain damage in monkeys by inducing perinatal asphyxia might seem inconsistent with this view, but in fact their findings support it, because many of their monkeys died and almost all of the survivors had no neurologic abnormalities. A 1984 Oxford study produced still more evidence that CP is rarely the result of birth asphyxia. A failure of medical personnel to react to evidence of intrapartum hypoxia and asphyxia was followed by a greater-than-expected frequency of neonatal apnea and seizures, but not of CP.²²

Have obstetrical and neonatal clinical advances since 1966 when the last CPS child was born made the findings of the

current study obsolete? Probably not, because the advances that have reduced fetal and neonatal mortality in the intervening years have not produced a corresponding decrease in the frequency of CP.^{31,33-39} All the children with CP in the present study were born full-term, and it is unlikely that current obstetrical and pediatric managements could have prevented their CP, because most of the disorders that damaged their brains took place long before labor and delivery and were unrecognized at the time the damage occurred. Electronic fetal monitoring has come into widespread use since the CPS, and many hope that it is preventing some cases of CP by warning of asphyxia or hypoxia before irreversible brain damage takes place.

There is no convincing evidence that this hope is being realized.²¹ In a large, well-controlled study, MacDonald et al³⁸ used electronic fetal monitoring both to identify intrapartum asphyxia or hypoxia and to intervene to protect fetuses from further risk. These interventions reduced the frequency of neonatal seizures, but did not affect the frequency of subsequent neurologic abnormalities. These findings have their counterpart in the present study, where neonatal seizures were 35% more frequent when oxytocin was administered without a corresponding increase in the frequency of CP.

Finally, the findings of the present study underscore the importance of making accurate measurements and

observations on neonates to avoid misattributing nonasphyxial CP to birth asphyxia. Carefully recorded observations of a neonate's kidney, heart, and lung function can help to determine whether birth asphyxia caused CP, because birth asphyxia that is severe enough to damage the brain usually damages the kidneys, the lungs, and often the heart.^{2,19,47,61,62} The results of ultrasound examinations, computerized radiographic tomography, and magnetic resonance imaging studies can also be of value in distinguishing between CP of asphyxial and nonasphyxial origin.

Jacques Benichou, Michell H. Gail, and David Pea of the National Cancer Institute, Rockville Md, kindly provided the software for computing the confidence limits of the attributable risk estimates

Book Review

Hypnosis and Hypnotherapy With Children, by Karen Olness and G. Gail Gardner, 431 pp, \$39, New York, NY, Grune & Stratton, 1988.

Hypnotherapy in the care of children has recently enjoyed a renaissance of interest and attention. Anecdotal reports of pediatric applications have been intriguing, yet hypnosis as a therapeutic modality in pediatrics has, with notable exceptions, remained out of the mainstream of medical understanding and use. Karen Olness, a pediatrician, and the late Gail Gardner, a psychologist, have, in this book, challenged clinicians to reexamine the potential contribution of hypnotherapy toward the primary care of a broad spectrum of pediatric conditions.

In a field so relatively new and untried, the authors have provided a general guide to the field, including introductory information, clinical applications, and research progress to date. The first chapters are devoted to the history of hypnotherapy and children, as well as to a review of the fundamentals of hypnosis and hypnotic responsiveness in children. There is a detailed chapter on hypnotic induction techniques. The body of the book covers applications for psychological and habit disorders, learning problems, pain control, and medical and surgical problems.

For the pediatric clinician, therapeutic applications are described for a variety of disparate conditions, including enuresis, encopresis, tic disorders, asthma, hemophilia, juvenile rheumatoid arthritis, headaches, cyclic vomiting, preparation for medical and surgical procedures, and coping with chronic or terminal illnesses. There are, as well, excellent discussions that help the clinician place this modality in context (eg, indications, limitations, and contraindications for use and the optimal involvement of parents). For the researcher, this book will continue to be a basic source. Each chapter is richly referenced. Studies cited range from case reports to well-designed experimental protocols.

For Olness and Gardner, hypnosis is defined broadly as "an altered state of consciousness" with focused attention and characteristic changes in cognition and receptivity. Hypnotherapy is seen as a treatment modality utilizing hypnosis but also relying on the skilled interventions of the clinician. The underlying mechanisms are acknowledged as not understood. A repeated theme throughout is that hyp-

nototherapy recruits and channels tendencies or "urges" present in every child, ie, to seek experience, mastery, social interaction, inner imagination, and wellness. Throughout the book the reader is admonished to view the hypnotic state as a talent that belongs to the child. The hypnotherapist is likened to a coach who helps develop this talent.

For the interested nonhypnotherapist pediatrician, two provisos apply. First, as a behavioral pediatrician not primarily trained in hypnotherapy (but the recipient of a 3-day workshop organized in part by one of the authors) I am impressed that the acquisition of hypnotherapy as a clinical tool requires live supervision. Too much of the technique relies on communication and interpersonal understanding to be learned solely from a text. The authors stress this point well.

Second, a dilemma arises with regard to the broader prerequisites for doing this sort of work. Olness and Gardner emphasize that a "hypnotherapist first must be a competent therapist." Their clinical descriptions and individualized therapeutic protocols belie their own in-depth understanding of child development and psychodynamic issues. At the same time, the care they describe is, for the most part, within the context and bounds of pediatric practice. The question, then, is whether current standard training in pediatrics provides the fundamental knowledge and skills necessary to acquire expertise in hypnotherapy. The authors do not address this directly, and readers will need to make their own assessment.

In sum, *Hypnosis and Hypnotherapy With Children* remains a pioneering effort by a pair of gifted and committed clinician-researchers. It persuasively presents the case that all children possess inner resources that may be tapped in the service of optimizing health and mastery. It is further evidence of the indivisibility of the links between mind and body, imagination and physiologic response, and play and well-being.

The Pregnant Adolescent Prostitute

Robert W. Deisher, MD; James A. Farrow, MD; Kerry Hope, MSW; Christina Litchfield, RN, BSN

• The issue of teenage pregnancy is one of paramount concern and has been covered extensively in the professional literature. Teenage prostitution, as well, has drawn attention from medical and social science researchers. An increasing number of teenage prostitutes are becoming pregnant and delivering infants. These young women constitute a high-risk group that merits professional investigation and requires sensitive clinical approaches. We describe the pregnancy and early postpartum outcomes of 61 teenage prostitutes (age range, 13 to 18 years) in Seattle, Wash, during the period from January 1987 to February 1988. The subjects' environment, prenatal care, drug use, contraceptive practices, repeated pregnancies, and risk for sexually transmitted diseases (including acquired immunodeficiency syndrome) are discussed. Two case examples are used for illustration.

(AJDC. 1989;143:1162-1165)

Teenage prostitution is a subject that has received relatively little attention in the professional medical literature. Even less attention has been given to the fact that many young women become pregnant in the course of their prostitution activities. It is estimated that at least 50% of all juvenile prostitutes have been pregnant at least once.¹ Adolescent pregnancy and child bearing, on the other hand, are subjects on which much has been written.¹⁻⁴ Specifically, there are studies on the effects of sexual abuse on young women,⁵ prevention,⁶ education,⁷ long-term outcome for adolescent mothers,^{8,9} and contraceptive behavior¹⁰ that emphasize the seriousness of the problem in contemporary society.

Existing literature on teenage prosti-

tution has focused on runaways and street life,¹¹ victimization,¹² legal considerations,^{13(p189-227)} and attempts at rehabilitation.¹³ In 1980, Weisberg¹ acknowledged that many adolescent prostitutes become pregnant. However, there is almost no reported data available on pregnant teenage prostitutes or pregnancy outcome.

The problems of teenage prostitution, when coupled with the risk of pregnancy and motherhood, are further exacerbated by the violent life-style of the streets and now by the risk of acquired immunodeficiency syndrome. Furthermore, those professionals who work with children and adolescents must be made aware of the victimization of these young people, not only by their families, pimps, and clients, but by a society to whom they are almost totally invisible, and by whom, if recognized, they are held responsible for their life situation. Abuse during childhood is a common factor in the lives of young people on the street. The negative sexual experience of early abuse often leads to a self concept of being sexually "devalued" and "spoiled," a "bad girl" who turns to a delinquent subculture for social acceptance, status, and income.^{12(pp812-855)}

Given the identified risks for child bearing at a young maternal age (ie, poor nutrition, substance abuse, and lack of prenatal care), it is difficult to find a risk group to which these young women do not belong.

It is estimated that there are 1 million runaways each year in the United States.^{12(p19)} The estimated number of adolescent prostitutes in the United States is 900 000; roughly two thirds or 600 000 of these prostitutes are female.^{12(p15)} A rough estimate of the number of young women in Seattle, Wash, under 18 years of age who are engaged in prostitution is thought to be between 400 and 500. This number is probably no greater than that which would be found

in any other city of comparable size.

Health and social services, if sought at all, are obtained by this population only for acute or crisis problems in busy emergency departments. Often these patients are not identified as prostitutes because complete medical histories are not taken or the appearance of the young woman does not fit the health professional's image of a prostitute. Furthermore, there is a reluctance among health professionals to confront the reality of teenage prostitution. These young women, when they have contact with health care providers, have been able to pass through the system almost unnoticed.

The adolescent medicine program at the University of Washington, Seattle, has provided medical care to street youth for the past 15 years through a network of free night clinics located throughout the downtown area of the city.

We have frequently encountered young women engaged in prostitution who present at clinics expressly for the purpose of determining pregnancy status. A large proportion are found to be pregnant. The study results reported herein describe our experience with 61 of these young women during the course of their pregnancies and during the early postpartum period.

The purpose of the project was to gather descriptive information on a sample of 61 young women and to facilitate access to appropriate health and social services. Two case examples are presented with a descriptive summary of the characteristics of the young women and their pregnancies.

CASE STUDIES

CASE 1.—Jean was a 17-year-old black teenager who was born in the Seattle area. She was relinquished by her natural mother, who was a drug addict and a prostitute. Jean's natural father was a drug addict.

Jean was adopted at 3 years of age by a

Accepted for publication February 13, 1989.

white family. During her 10 years with this adoptive family, she was both sexually and physically abused. The sexual abuse began at 5 years of age by her adoptive father. By 11 years of age, she began running away from home regularly. She was then placed in numerous foster care homes from which she ran away. Jean dropped out of formal education at the age of 14 years, met her current pimp/drug dealer/boyfriend, and began prostituting. She was taken from Seattle to the San Francisco Bay area for a number of months to "work." She returned to Seattle, where she had a series of pimps/boyfriends. Recently, she became reinvolved with her original pimp.

Jean began experimenting with alcohol and drugs at 12 years of age and has been a regular cocaine and intravenous drug user for the past 4 years. She has been pregnant four times. Three of these pregnancies ended in abortion. The other pregnancy was carried to term.

During the pregnancy, Jean continued to use drugs and alcohol supplied by her pimp. She also continued to prostitute until late in her third trimester. She received no prenatal care. She presented in the emergency department of the hospital in labor.

Jean was allowed to take the infant from the hospital with no child protective service report being filed and no referral to a public health nurse.

Her relationship with her pimp has been very violent. This violence, as well as her drug addiction, has been used to control and intimidate Jean. She has been severely beaten by her pimp and he recently broke her jaw, which led to her hospitalization. She miscarried at that time. Jean considered filing charges, but was afraid for her child because child protective services had given temporary custody to the pimp's mother.

At this point, the young woman has lost custody of her child and is considering relinquishing parental rights. She has no stable living conditions and is continuing to prostitute and use intravenous drugs. Recently, she became reinvolved with her original pimp.

CASE 2.—Mary was a 16-year-old white teenager at the time of this study. She was born in the Seattle area to a mother who was a drug addict and alcohol abuser. Mary's natural mother lives in the Seattle area but is not allowed any contact with her children. Mary's natural father is unknown. Two sisters, aged 17 and 18 years, live in the Seattle area; both are involved in prostitution. One sister is pregnant, the other just delivered.

Mary's early home life was very chaotic. She and her sisters were separated at an early age due to sexual abuse in the home by her mother's customers. The girls were placed in foster care with relatives. Mary left

foster care at age 11 years and began prostituting for drugs and a place to sleep. Mary has a history of violent behavior and suicide attempts.

Mary has had numerous pimps and has traveled extensively up and down the West Coast. She has had the same pimp for the past 2 years. Mary became pregnant for the first time at age 14 years and received no prenatal care during her pregnancy. The child was removed from her custody and placed in long-term foster care. She became pregnant a second time at age 15 years. Again, she received no prenatal care and delivered in the back seat of a taxi bringing her to the hospital. She prostituted heavily for the first 8 months of the pregnancy and free-based cocaine up to the time of delivery. Child protective services intervened while the infant was still in the hospital.

The child was placed with Mary's eldest sister, who was pregnant at the time. Mary attempted to regain custody of her child but was mandated to complete drug treatment to accomplish this. She failed to complete drug treatment and has not followed up on her efforts to regain custody. The child is now in state foster care. Since losing custody of her child, Mary has been moving from place to place with her pimp.

SUBJECTS AND METHODS

To carry out the study, the Washington State Health Department, Bureau of Parent and Child Health, provided funding for a part-time social worker for case findings, follow-up, and data collection, as well as a part-time public health nurse to provide health and outreach services to these pregnant adolescents. These data were collected in Seattle from 1987 through 1988. The study data presented here focus primarily on the background and status of the young women.

The 61 subjects in this study were young women engaged in prostitution, 13 through 18 years of age, who were either pregnant or had recently delivered. Age and racial distribution are summarized in Table 1. New cases were identified by the project social worker in a variety of ways. Thirty-one of the 61 subjects interviewed between January 1987 and February 1988 were identified at the medical clinic in the King County Juvenile Detention Center, Seattle. Many young women are arrested for prostitution-related activities and are found to be pregnant at the time of their admission for health screening. The remaining 30 subjects were referred by a number of health and social service agencies serving street youth in the Seattle area. Due to the large number of referral sources, we believe that the young women in this study are an accurate representation of pregnant adolescent prostitutes in the Seattle area.

The social worker administered an open-

ended questionnaire to the project participants, which had been piloted in a university teen clinic with young teens who were pregnant. The questionnaires included discussion of family background and social history, sexual/physical abuse information, pregnancy status, health care status, drug use, child-bearing history, education history, living arrangements, contraceptive practices, and child protective services involvement. Examples of questions included, "Have you used drugs or alcohol during this or previous pregnancies?" "Have you used drugs or alcohol since delivery?" "Have you ever tried any form of birth control?" "If you are pregnant, what options for the pregnancy have you considered?"

The public health nurse, who joined the project in October 1987, initially contacted the young women for a pediatric and obstetric health needs assessment. Referrals were then made for prenatal or postnatal care, the Women, Infants and Children nutrition program, drug treatment, and other community services. The nurse also continued to follow up subjects, provide education and counseling, and monitor services. The public health nurse and the social worker met regularly for data collection and review, exchange of information, and joint planning of follow-up services.

RESULTS

A number of shared experiences or characteristics were common to the majority of subjects. None of the young women in the study sample came from an intact family. Child protective services had been involved with the majority of them as younger children. Many of the young women had been removed from their natural homes and placed in foster care.

Although fewer than half of the young

Table 2.—Contraceptive Use and Initiation of Prenatal Care

	No. (%) of Subjects

Month initiated	
3rd	2 (5.9)
4th	6 (17.6)
5th	10 (29.4)
6th	11 (32.4)
7th	4 (11.8)
8th	1 (2.9)

women admitted to having been physically or sexually abused as children, 37 refused to provide any detailed information to the interviewers about this sensitive subject. Fifteen (25%) of the subjects had mothers who were or are currently involved in prostitution. In some cases, the subjects' mothers had introduced them to prostitution.

Sixty-seven percent (n=41) of the sample had a family history of alcohol and other drug abuse. Several subjects described having been given alcohol and other drugs as children and being sexually abused by their mother's partners in the context of parental alcohol and other drug abuse. Sixty-five percent (n=40) of the young women in this sample had a known history of serious alcohol and other drug abuse. The entire spectrum of drug use has been reported by young women involved in the prostitution/street life-style. Other researchers have described a drug use rate among this population of 66% (n=10), which is consistent with that reported by our sample.¹⁶⁽¹⁷⁾

A lack of adequate education was common. Ninety percent (n=55) of the young women in the study were not in school at the time these data were collected. Of the 10% (n=6) who were in school, 3 were in alternative school programs and 3 were in general equivalency diploma programs. Due to the lack of sufficient education, emotional support, job skills, and social skills and the chaotic life-style, a hopelessness often pervades these young women's lives. Forty-one percent (n=25) of the subjects reported seriously considering or having attempted suicide within the past 12

months. Pregnancy appears to make them more vulnerable to depression and to manipulation by pimps and others on the street.

These young women came from varied socioeconomic and cultural backgrounds. Whites and blacks accounted for the largest percentage of subjects (Table 1). Living conditions for this group of young women varied widely. Some had somewhat stable living conditions. Others moved frequently, if not daily. Living situations at the time of the study are summarized below:

Living Situation	No. (%) of Subjects
Pimp/boyfriend/ husband	19 (31.1)
Mother/other relative	18 (29.5)
Social services/ detention	9 (14.8)
Female friends	6 (9.8)
Street	2 (3.3)
Not known	7 (11.5)

The young women in the study acknowledged that most of their pregnancies were unplanned. Moreover, they stated that they did not want to become pregnant again. Despite this, when asked if they were currently using contraceptives, most admitted that they were not using them or used them only sporadically (Table 2). Condoms were not used consistently, in part due to their unavailability at the time, the cost, or their customers' willingness to pay more if they would forego condom use.

Seventy-nine percent (n=48) of the young women reported having no involvement with the father of their child, and some were not sure of the father's identity. Thus, they expect and receive no financial or emotional support from him. The general lack of health care and specifically the lack of prenatal care is another common problem for these young women. On average, subjects in this study who received any prenatal care initiated that care at the end of the second trimester and made two prenatal appointments. At the conclusion of the study period, 38 (67%) of the 55 infants born to the study participants had been referred to child protective services. Most referrals were made prenatally or at the time of delivery by medical or mental health personnel. Forty (66%) of the 61 young women in the study had current involvement with

child protective services. The number of births to the young women who delivered is summarized below:

No. of Children (n=42)	No. (%) of Subjects
1	32 (76.2)
2	8 (19.0)
3	1 (2.4)
4	1 (2.4)

At the time of the study, 18 (29.5%) of the young women were pregnant, 41 (68.9%) had delivered, and 1 had died. A total of 55 infants were delivered and 4 infants (7.8%) died.

COMMENT

The teenage prostitutes in this study had many problems, as demonstrated by the results of this study, and illustrated by the case examples. The adolescents presented were typical in that once pregnant, a few would request an abortion, but the majority continued with the pregnancy. Relinquishment was almost totally rejected by the group; many, in fact, were glad to be pregnant, and felt that this would make their lives better. Despite wishing to keep their infants, most of the young women had no child care skills or any realistic idea of where they would live or how they would support their child. As a result, they received late or no prenatal care, lived in unhealthy environments and were erratic contraceptive users.

Teenage prostitutes present a challenge to social service and medical personnel alike. Their lack of trust of adults and authority figures often interfere with the establishment of a helping relationship. The teenagers' suspicion of adult motives, their transient and often violent life-style, their dependence on drugs, and their need to drop out of sight, often due to life-threatening circumstances, further their isolation and mistrust. Access to these teenagers by helping professionals is often barred by the controlling adult figure in their life. This person may be a pimp, an abusive boyfriend, or a relative, as was the case with the majority of our subjects.

When the element of prostitution is added to teenage pregnancy, a number of new factors must be considered in offering services. Some of the important areas to be addressed are sexual abuse, drug dependence, malnutrition, violence of a street-based life-style, sex

ually transmitted disease, (including acquired immunodeficiency syndrome), and the stress of the life-style combined with a lack of coping and social skills. Danger to the unborn or recently delivered child is ever present.

There was an 8% perinatal mortality rate among infants born to our study population. These infants face being born addicted to drugs, testing positive for human immunodeficiency virus (HIV), with birth defects or other congenital anomalies and prematurity and low birth weight. Infants living with their teenage mothers often face neglect and abuse at the hands of their parent or their mother's pimp or boyfriend. Despite the fact that many of the infants in our sample were removed from their mother's custody, they were frequently placed with the girl's mother, in whose home the girl may still be living while prostituting. When the child is not removed from the mother's custody, we have found that having an infant does not promote stability in her life. These young women usually continue with prostitution, drug involvement, and a destructive life-style. Many return to the streets within days of delivery.

Research indicates that young delinquent prostitutes exhibit considerable ignorance about sexuality, contraception, and sexually transmitted diseases (ID Tanabe and JA Farrow, unpublished data, 1989). Pregnancy seems to have little reality for them. Whether they are traumatized by their early experiences, involved with alcohol and

other drugs, or just developmentally immature, those seen in our clinics often do not come to terms with their pregnancy until the time of delivery. This disassociation with their condition appears to relate to the fact that they are often forced to continue in prostitution throughout their entire pregnancy. Furthermore, they are often totally unprepared to cope with the added responsibilities that a pregnancy imposes.

This population and their unborn infants are at an extremely high risk for HIV infection. Rosenberg and Weiner¹⁴ believe that adult prostitutes are not at high risk for acquired immunodeficiency syndrome due to their sexual activities. The young women in our study would appear to be at high risk. The prevalence of intravenous drug use among them and their partners as well as the large number of sexual partners (as many as 120 per month) make them vulnerable to HIV infection. Testing for HIV is not being requested by many in this population and the HIV status of our study population is currently unknown. No actual cases of acquired immunodeficiency syndrome in Seattle have been diagnosed among juvenile female prostitutes. As of this time, HIV positivity among adult female prostitutes in the King County Jail is 2% (Hunter Handsfield Office, Harborview Medical Center, Seattle).

Provision of preventive health care and social services to this population is especially difficult. Community-based, case-management approaches are indicated. Health services must be offered

in a manner that builds trust and eliminates access barriers. Health screening and patient education are best provided through an outreach effort that engages these young women in the community, in institutions, and on the street. Liaison with existing adolescent health services is essential to provide needed obstetric services and treatment for sexually transmitted diseases, drug abuse, and physical trauma.

Many of these young women require emotional support and safe shelter during pregnancy to improve pregnancy outcome. Homes for unwed mothers that formerly existed have been closed in an attempt to reduce the stigma, to mainstream this population, and to streamline services. Unfortunately, this forces the young woman to stay with her pimp/boyfriend or to continue prostituting to provide food and shelter.

More study is needed to characterize this growing population and their health problems and needs. Health and social services professionals must become much more aware of the unique problems of these vulnerable adolescents, and training must be provided to improve the capabilities of public health professionals to address them. More must be learned about the infants of these adolescents in terms of developmental status and pediatric health care needs. The problems of the pregnant adolescent engaged in prostitution can no longer be ignored by health professionals. The stakes have become too great for young mothers and their infants.

Adolescent Contraceptive Use and Parental Notification

Efstathios Demetriou, MD, MPH, David W. Kaplan, MD, MPH

• Little research exists regarding the relationship between family communication and the sexual behavior and contraceptive use of adolescent females. A self-administered questionnaire was used to survey 196 adolescent females regarding communication with their parents about sexual issues and their reaction to proposed parental notification of the dispensing of prescription contraception. Parents of 80% of the subjects who were sexually experienced were aware of this activity. Parents of 80% of those subjects who had used contraception were aware of this use; 59% of these subjects informed their parents before their family planning visit. The majority of female adolescents (57%) were unwilling to communicate with their parents about sexual issues; 64% felt they should be able to receive prescription contraception without parental knowledge. Communication regarding sexual issues was related to lifetime contraceptive use. Eighteen percent of the sexually experienced subjects would not allow their parents to be notified of their family planning visit; 86% would use less effective contraception if family planning services were not sought. Our findings suggest that a parental notification policy will not compel all adolescents to inform parents about their contraceptive use; most adolescents will resort to less effective contraceptive methods.

(AJDC. 1989;143:1166-1172)

Since the early 1970s, a dramatic increase in premarital intercourse among adolescents has occurred. One national survey found that in 1979, 46% of all 15- to 19-year-old females who had

never been married were sexually experienced, compared with 28% in 1971.¹ The risk of premarital pregnancy has similarly risen. In 1984, there were just over 1 million pregnancies and 470 000 livebirths to women younger than 20 years.² Although some 367 000 unplanned pregnancies are stopped annually by federally funded family planning services,³ many more could be prevented if adolescents consistently used contraception.

Adolescents may use contraception less effectively when parents are unaware they are having sexual relations and would disapprove if they knew.^{4,5} Several studies suggest that communication between mothers and their daughters regarding contraception is related to more effective contraceptive practice by the adolescent.⁶⁻⁸

Several states have considered or enacted statutes and one federal agency has attempted to implement regulations in recent years requiring parental notification by agencies that provide prescription contraceptives to unemancipated adolescents. The ensuing debates highlighted the fact that little research exists regarding the relationship between family communication and adolescent use of contraceptive services. One study indicated that 23% of all females younger than 18 years enrolled in a family planning clinic would stop coming and use less effective contraception if such a rule were implemented.⁹ Another study found that 43% of teenage girls attending a family planning clinic for the first time cited fear of parental notification as a major reason for their delay in seeking services.¹⁰

We utilized a self-administered questionnaire to survey a group of adolescent females presenting to a general adolescent medicine clinic regarding their communication with their parents about sexual issues and their reaction to the

proposed parental notification of the dispensing of prescription contraception.

PATIENTS AND METHODS

Unmarried nulliparous female patients 15 to 18 years of age who attended the Adolescent Clinic of Oklahoma Children's Memorial Hospital, Oklahoma City, for health care from February 1983 to December 1983 were eligible to participate in the study. The clinic provides primary care to indigent teenagers 13 to 21 years of age from the Oklahoma City area and offers care to physician- and self-referred patients from throughout the state. A preliminary version of the data collection instrument was piloted with 15 subjects. The instrument was reviewed by two experts in adolescent health care for content and was reviewed by a public health expert experienced in questionnaire design for item construction. No external checks were made regarding the validity of the subjects' responses. Test-retest reliability was not assessed. A convenience sample of 196 subjects was included in the study; 1 patient declined to participate. Written informed consent was obtained; confidentiality was assured. This study was approved by the Institutional Review Board of the University of Oklahoma Health Sciences Center, Oklahoma City.

A self-administered, printed questionnaire was used for data collection. Reading ability was assessed using a paragraph at a sixth-grade level of difficulty. One investigator (E.D.) reviewed the responses with each participant. Demographic information requested included age, ethnicity, religion, parent with whom subject resided, family income, parents' educational level and occupation, city or town of residence, present school attendance, grade appropriateness for age (based on Bureau of the Census criteria), highest grade completed, grade-point average, and reason for the clinic visit. The following sexuality-related information was collected: past and present sexual activity, age at first sexual experience, parents' awareness of sexual activity, past and present contraceptive use, age at first contraceptive use, duration of current contraceptive use, parents' awareness of contraceptive use, and the reason contraceptives were not

being used. Each subject was also asked to comment on the following: ability to communicate with parents regarding sexuality-related issues, whether teenagers should be able to receive prescription contraception without parental notification, course of action if parental notification were required to receive these services, and the course of action if services that provided contraceptives were not sought. A Hollingshead Two-Factor Index of Social Position was calculated for each subject. This index, based on parents' occupation and educational level, ranged from 1, representing the highest social position, to 5.

Mean and range, or mean \pm 1 SD if the variable were normally distributed, were used as measurements of central tendency. Univariate analysis utilizing the χ^2 and Student's *t* test identified independent variables related to the dependent variable of interest. Because two groups were compared for multiple independent variables, relationships with a $P \leq .01$ were considered significant to reduce type I error. Univariate relationships between independent and dependent variables with a $P \leq .10$ are shown in Tables 1 through 6. These independent variables were used to perform a multiple logistic regression analysis. This analysis incorporates intercorrelations among independent variables and selects those variables that best predict the outcome variable. This regression model is more appropriate for use with dichotomous dependent variables than ordinary least-squares regression. A $P \leq .05$ was considered significant. The regression coefficient β and the *P* value are shown for each significant independent variable. Software was used to perform the data analysis.

RESULTS

Demographic characteristics are given in Table 7. Subjects were a mean of 16.0 ± 1.1 years of age, mainly white (57%), Protestant fundamentalist (81%), and of lower socioeconomic status (56%). Sexuality-related characteristics are given in Table 8. Sixty-five percent were sexually experienced, and 53% were sexually active (defined as sexual activity within the preceding 2 months). Of those who were currently sexually active, 48% were using effective contraception (oral contraceptives, foam, or condoms). The following reasons were given by the 55 subjects who were not using effective contraception: didn't get around to it, 20%; concerned about side effects, 16%; may be or wants to be pregnant, 13%; worried parents would find out, 11%; didn't know where to go, 11%; inconvenient to use, 9%;

didn't feel contraception was needed, 9%; couldn't afford contraception, 4%; boyfriend objected to contraceptive use, 2%; and no reason given, 6%.

At least one parent of 80% of those teenagers who had used contraceptives was aware of their use. The majority (59%) of teenagers informed their parents before their first family planning visit; 32% reported a parent had accompanied them. The following reasons were given by the 15 responding subjects who had not informed their parents: afraid their parents would be angry, 47%; none of their parents' business, 20%; they had just started us-

ing birth control, 13%; no reason, 13%; and hadn't thought about it, 7%.

A minority of teenagers (43%) felt they were able to communicate with their parents regarding sexual issues; almost two thirds felt they should be able to receive prescription contraception without parental knowledge. Twenty percent of all respondents and 18% of the sexually experienced subjects would not allow their parents to be notified and would not seek family planning services if parental notification were mandatory. Eighty-seven percent of those who would not allow their parents to be notified would remain sexual-

ly active—56% said they would use barrier contraceptives and 31% said they would have unprotected intercourse. Almost three fourths of all the respondents said they would remain sexually active even if they did not seek family planning services.

Subjects were divided into two groups for further analysis based on previous sexual experience. Demographic factors that correlated with sexual experience are shown in Table 1. Religious background and ability to communicate with parents about sexual issues were not related to sexual experience. Sexually experienced subjects were more likely to feel they should be able to receive prescription contraceptives without parental knowledge and were less likely to refrain from sexual activity should they not seek family planning services. The association between sexual experience and demographic and sexuality-related characteristics was further evaluated using logistic regression analysis. The characteristics significantly related to sexual experience were age ($\beta = .48$, $P = .02$), whether the subject was a school dropout ($\beta = 2.30$, $P = .05$), the Hollingshead

Index ($\beta = .39$, $P = .05$), and willingness to abstain from intercourse if family planning services were not sought ($\beta = -1.97$, $P = .0002$) ($\chi^2 = 60.11$, $df = 10$, and $P < .0001$ for the entire model).

Responses of sexually experienced subjects were examined according to whether these subjects had ever used prescription contraceptives (Table 2). Contraceptive users had parents who were aware of their sexual activity and were willing to communicate with their parents regarding sexual issues. Race, religion, socioeconomic status, school achievement, and age at first intercourse were unrelated to contraceptive use. Only age ($\beta = 1.00$, $P = .0005$), age of first sexual experience ($\beta = -.65$, $P = .002$), and parents' awareness of sexual activity ($\beta = .70$, $P = .03$) were predictive of prescription contraceptive use by logistic regression ($\chi^2 = 32.43$, $df = 6$, and $P < .0001$ for the entire model).

The willingness of subjects to communicate with parents regarding sexual issues was identified as an important outcome (Table 3). Those who were able to communicate were more likely to use

prescription contraceptives and have parents who were aware of their sexual activity and contraceptive use. This group also demonstrated a trend toward the belief that parents should be informed of their visit to a family planning facility before its occurrence ($P = .08$). Age, religion, socioeconomic status, sexual activity, age at first intercourse, age at first contraceptive use, or interval since first contraceptive use were not related to communication. Multivariate analysis revealed that only the belief that adolescents should be able to receive contraception without parental knowledge ($\beta = -1.02$, $P = .01$) and a willingness to notify parents to receive prescription contraceptives ($\beta = 1.64$, $P = .005$) were related to a willingness to communicate ($\chi^2 = 48.12$, $df = 10$, and $P < .0001$ for the entire model).

The second important outcome variable was whether adolescents felt they should be able to receive prescription contraceptives without parental knowledge (Table 4). Those who answered affirmatively were more likely to be sexually experienced, were less willing to communicate with parents regarding sexual issues, and would not allow parents to be notified of their family planning visit. Logistic regression indicated that only a willingness to communicate with parents regarding sexual issues ($\beta = -.80$, $P = .05$), to allow parents to be notified of the family planning visit ($\beta = -3.24$, $P = .003$), and to abstain from intercourse if prescription contraceptives were unavailable ($\beta = -2.38$, $P = .0001$) were related to the outcome measurement of interest ($\chi^2 = 71.18$, $df = 8$, and $P < .0001$ for the entire model).

The willingness of teenagers to inform their parents of their family planning visit was another important outcome measurement (Table 5). Those who would do so were more likely to live in Oklahoma City proper, were willing to communicate with parents about sexual issues, and were less likely to desire prescription contraception without parental knowledge. Logistic regression analysis indicated that only a willingness to communicate with parents about sexual issues ($\beta = 1.79$, $P = .003$) and desire to receive prescription contraceptives without parental knowledge

($\beta = -2.86$, $P = .007$) were related to the outcome variable ($\chi^2 = 40.82$, $df = 7$, and $P < .0001$ for the entire model).

Finally, adolescents who indicated they would have unprotected intercourse if family planning services were unavailable were contrasted with those who would use barrier methods or would abstain from sexual relations (Table 6). Logistic regression indicated that only sexual experience ($\beta = 3.33$, $P = .002$) and a willingness to allow parents to be notified of the family planning

visit ($\beta = -1.20$, $P = .02$) were significantly related to the outcome variable ($\chi^2 = 34.73$, $df = 7$, and $P < .0001$ for the entire model).

COMMENT

Results from our study suggest that the majority of adolescent females who use our clinic would continue to attend if parental notification were required to receive family planning services. However, 18% of sexually experienced adolescents would not allow their parents to

be notified and would not come to the clinic under these circumstances; most patients would remain sexually active and would use less effective methods of contraception or none. The majority of sexually inexperienced subjects indicated they would abstain from intercourse; this finding reflects their inexperience with sexual issues and raises the question whether a parental notification policy might influence adolescents to delay sexual activity.

ters' sexual activity and contraceptive use was high among our study population. This was surprising, given the conservative values of the southwestern United States. Most parents found out about their daughters' contraceptive use directly from them. The majority of teenagers were able to inform their parents of their contraceptive needs before the family planning visit.

The majority of our patients felt they were unable to communicate with their parents regarding sexual issues, and almost two thirds of our patients felt they should be able to receive prescription contraception without parental knowledge. The interval since first contraceptive use and the duration of current contraceptive method use were no longer for those who were able to communicate with parents, suggesting communication does not improve once teenagers begin to use contraception. A larger percentage of those subjects who were

able to communicate with their parents informed them about their visit to a family planning facility before its occurrence, suggesting that preexisting communication may facilitate the initiation of contraceptive use.

Subjects from Oklahoma City were more willing to inform parents of their family planning visit than those from surrounding suburban areas. These less affluent adolescents use the Adolescent Clinic for primary care and may be less secretive with parents regarding sexual issues than adolescents from more affluent suburbs, who often come to the clinic for confidential family planning services.

Our results are similar to those reported by Torres et al,⁹ who found that 23% of teenaged girls attending a family planning clinic would stop doing so if parental notification were required. Twenty percent of our entire study group and 18% of our sexually experienced subjects would not attend. Torres et al⁹ found that only 9% of those who would stop attending would abstain from intercourse and 27% would have unprotected sexual relations. Of our subjects who would not allow their parents to be notified, only 13% would abstain from intercourse and 31% would have unprotected intercourse.

Previous studies indicate that 54% to 67% of parents were aware of their adolescent daughters' family planning visits.^{9,11} We found that a higher percentage of parents (80%) were aware of their daughters' contraceptive use. Furstenberg et al¹¹ reported that 56% of mothers found out about their daughters' contraceptive use before or at about the time of the first family planning visit; this is similar to our finding of 59%.

The study of Furstenberg et al¹¹ also found that those who informed their parents about their contraceptive use early on did not communicate more effectively about sexual issues. This contrasts with our data, which demonstrated a trend toward such a relationship. Furstenberg et al¹¹ reported that 39% of the adolescents attending a family planning clinic were able to communicate with their parents regarding sexual issues; we found 43% of our relatively unselected subjects could do so. We had expected better communication since it is those adolescents who

desire confidential services that most often use family planning clinics. Finally, these investigators showed that black teenagers reported better communication than white teenagers.¹¹ However, we found that blacks were least likely to communicate with parents about sexual issues.

Our findings of a positive association between parent-daughter communication and use of effective contraception are similar to other published results.⁶⁻⁸ A more recent study failed to demonstrate a relationship between continuous contraceptive use and effective communication.¹¹ Additional studies are necessary to delineate further the determinants of parent-daughter communication regarding sexual issues and to identify better the relationship between communication patterns and the commencement and continuation of effective contraception by teenagers.

An important limitation of our study is that parents were not interviewed regarding communication with their daughters about sexual issues or their

knowledge of their daughters' sexual behaviors. The perceptions of adolescents regarding these issues may differ considerably from those of their parents. Additionally, our findings are specific to a group of largely inner-city youth from a southwestern city and may not be generalizable to adolescents residing in other parts of the United States.

Our findings have significant implications regarding state and federal efforts to impose parental notification requirements on minors seeking contraceptive services. Although these findings suggest that parent-adolescent communication regarding sexual issues may facilitate the use of effective contraception, such communication seems to predate the visit to a family planning facility and probably cannot be created by legislative or regulatory means. A parental notification policy will not obligate all adolescents to inform their parents about their contraceptive use or stop them from having sexual relations. The end result may well be an increase

in the use of less effective contraception and unintended pregnancy. Parental involvement should be encouraged by family planning agencies where appropriate. Research suggests that clinics that encourage, rather than require, teenagers to inform their parents of their attendance have a significantly higher level of parental involvement.¹²

We found that most parents were aware of their adolescent daughters' sexual activity and contraceptive use. Communication between parents and daughters regarding sexuality was less prevalent. If parental notification were required to receive family planning services, a small but significant percentage of respondents indicated they would not attend our clinic and would resort to less effective contraceptive methods.

The software used to perform the data analysis in this study was supplied by SAS Institute Inc, Cary, NC.

Herbert L. Kayne, PhD, gave advice regarding the statistical analysis, and Patricia M. Demers, MS, MPH, provided editorial assistance.

• General pediatricians provide comprehensive care for many children with insulin-dependent diabetes mellitus. To assess and improve our ambulatory training program, we first evaluated diabetes-specific care behaviors by residents in their continuity clinics and then introduced a structured visit encounter form. Based on established guidelines provided to the residents, a chart audit indicated appropriate measurement of glycosylated hemoglobin 40% of the time, cholesterol 90% of the time, urine protein 50% of the

time, and thyroxine 66.7% of the time. Height was plotted 23% of the time, blood pressure was noted 66% of the time, and ophthalmologic referrals were documented 60% of the time. Requests for assistance from nonphysician members of a multidisciplinary diabetes team were minimal. After introduction of the structured visit encounter form, care behaviors did not improve. New training approaches to prepare general pediatric residents to provide excellent diabetes care are needed. (AJDC. 1989;143:1173-1176)

Insulin-dependent diabetes mellitus (IDDM) is one of the most common childhood chronic illnesses, affecting 1.8 of 1000 children aged 0 to 20 years.¹ Most general pediatricians, therefore, will encounter patients with IDDM regularly, and indeed several surveys²⁻⁴

suggest that general pediatricians in the United States provide a substantial portion of the medical care for children with IDDM. The typical pediatrician provides either complete or shared medical care to a median of 4 patients with IDDM.² Hence, for general pediatric training programs to provide adequate preparation, they need to include substantial experience in the outpatient care of patients with IDDM.

Published guidelines for training in general pediatrics call for inclusion of ambulatory training in diabetes care,⁵ and the majority of pediatric residency

programs include longitudinal IDDM care by residents.² A portion of this training at our center is accomplished in the general pediatric resident ambulatory care clinics (continuity clinics). In this setting, the resident has primary responsibility for his or her patients and reviews decisions with a general pediatric preceptor who is present at the clinic. Involvement in the care of these patients by diabetes team members, including endocrinologists, nurse practitioners/educators, dietitians, and social workers, is at the discretion of the resident and preceptor. Therefore, the continuity clinic is an appropriate site for evaluating the diabetes-related care practices of residents. Similarly, it provides a setting where specific interventions to improve care and/or training can be evaluated.

Under the auspices of the Indiana University Diabetes Research and Training Center, we have begun a series of studies designed to evaluate training of general pediatric residents in the continuity clinic setting. As a preliminary step, we conducted a chart audit of patients followed up in the conti-

Reprints not available.

nuity clinics to determine the extent to which residents were following current care guidelines. The results, discussed below, documented deficiencies in adherence to several areas of patient care guidelines, thus indicating a need for intervention.

Previous investigations have shown that reminder systems incorporated into either charts or databases have increased residents' adherence to recommended care guidelines.^{6,8} A study at our center found that a computerized reminder system available to general internal medicine residents increased residents' adherence to preventive health care guidelines.^{6,7} This type of system was not available, however, in the pediatric continuity clinics; nor is it generally available nationally in either training or practice settings. To develop an analogous intervention that could be easily applied in a variety of settings, we created a structured IDDM visit encounter form for residents.

Increased compliance with American Academy of Pediatrics' guidelines for physician care activities and data recording behaviors has been demonstrated with the use of a structured age-oriented patient encounter form.⁸ Based on this work, we hypothesized that by providing a visit flow sheet outlining care guidelines on which data collected during the clinic visit are recorded, residents would be immediately reminded of recommended care guidelines, and thus adherence to these guidelines would improve. Our report describes the implementation and evaluation of this intervention.

MATERIALS AND METHODS

Resident Training

Residents caring for patients with diabetes in their continuity clinics were responsible for comprehensive care of one or two children. Each resident was given a diabetes handbook that provided guidelines for insulin and dietary management, the approach to treatment of patients in poor metabolic control with or without recurrent ketoacidosis, appropriate monitoring for metabolic control, screening and treatment of risk factors, such as hypertension and hyperlipidemia, diabetic complications, guidelines for obtaining physical and laboratory measurements, psychosocial issues of diabetes, and patient education. Several lectures each year dealt with inpatient and outpatient management, including review of the guidelines in the

handbook. Most second-year or third-year residents participated on the endocrine service, which involved inpatient and outpatient IDDM management and close interaction with a multidisciplinary team. Portions of the clinical care program have been described previously.^{9,10}

Development of the Structured Visit Encounter Form

A structured IDDM visit encounter form was developed to serve educational and data collection functions, as well as to provide residents with algorithms for laboratory and physical evaluation. The final form was agreed on by all members of the multidisciplinary team and two general pediatricians. Questions were divided into four categories: patient history, diabetes-specific physical findings, laboratory tests to be ordered with results from the previous visit, and the physician's evaluation and plan. Included in the history were questions pertaining to insulin adjustment, diet, exercise, and psychosocial issues.

Reminders of the appropriate frequency of laboratory tests, guidelines for obtaining further tests, and checklist opportunities for psychosocial, educational, and dietary referrals were also included. Guidelines for the optimal frequency of evaluations were those listed in the physician's diabetes handbook. Results of blood glucose self-monitoring were to be evaluated at every visit. Blood pressure, height (for patients under 14 years of age), and weight measurements were to be obtained every 3 months and plotted on a growth chart. Glycosylated hemoglobin measurements were to be obtained every 3 months. Serum cholesterol, serum thyroxine, and urine protein levels were to be measured at least yearly. An ophthalmology referral was recommended yearly for patients with diabetes of greater than 5 years' duration. These recommendations preceded and are similar to the recently published guidelines of the American Diabetes Association.¹¹

After the baseline evaluation of diabetes care, the structured visit encounter form was formally introduced into the continuity clinic setting. A memo was distributed to all residents directing them to use the form with their diabetic patients. Forms were placed in the charts of all diabetic patients at each visit by clinic personnel.

Evaluation

Charts of 30 patients followed up by 23 residents were audited for the period before the introduction of the structured visit encounter form to assess the level of care provided by the residents in their continuity clinics. The period covered was 9 months from October 1, 1985, to June 30, 1986. Tests

and referrals recommended annually were audited back 3 months to July 1 to encompass 1 year's duration. The audit form was used to record whether glycosylated hemoglobin, urine protein, serum thyroxine, or cholesterol measurements had been performed. Referrals to the ophthalmology department and documentation of routine care, including the plotting of height on a growth chart and the measuring of weight and blood pressure, were also included in the audit. In cases where there was no written physician order but there was a laboratory result in the chart or documentation of a visit to the ophthalmology department, it was recorded as if the physician had ordered the test or made the referral.

After the introduction of the encounter form, charts of 45 patients followed up by 29 residents were audited using the same methods and same audit form as was used in the baseline audit. The period was from October 1 through June 30 of the year following the initial audit. Again, annual laboratory tests and ophthalmology department referrals were audited back 3 months for a total 1-year evaluation period. Laboratory values, referrals, and height, weight, and blood pressure determinations not documented on the encounter form but documented elsewhere in the chart were included in the audit as if they had been documented on the patient encounter form.

Analysis

Adequacy of care was assessed by the frequency with which documentation existed to demonstrate that residents reviewed blood glucose results, obtained relevant physical findings, ordered appropriate tests, made ophthalmology referrals within the period recommended, and made referrals to multidisciplinary diabetes team members. The frequencies of these recommended behaviors were compared before and after introduction of the encounter form using Fisher's Exact Test.

Metabolic control was assessed by total stable glycosylated hemoglobin levels (normal, 4.6 to 8.0).¹² Mean glycosylated hemoglobin levels were calculated for each patient and audit period. Significance in glycosylated hemoglobin decrease was determined using a paired *t* test.

RESULTS

Frequencies of resident compliance with care recommended at 3-month and yearly intervals are shown in Table 1. Frequencies of referrals to diabetes team members are shown in Table 2. Before the encounter form was introduced, self-monitored blood glucose levels were documented, and a weight

Table 1.—Frequency of Recommended Resident Behaviors Before and After Introduction of the Structured Encounter Form*

	Diabetes Management		P†
	Before Form	After Form	
Yearly			
Cholesterol levels measured	90	66.7	.027
Urine protein values measured	50	55.6	.814
Ophthalmology referral	60	55.6	.813
Thyroxine levels measured	66.7	68.9	.999
Every visit			
Blood pressure measured	66	46.7	.012
Height plotted	23	27	.837
Weight noted	100	99	.601
Home blood glucose results reviewed	100	99	.999
Glycosylated hemoglobin levels measured	40	46.7	.639

*Values are given as percents.

†Significance was measured using Fisher's Exact Test.

Table 2.—Referrals Made to the Multidisciplinary Diabetes Team Members by Pediatric Residents for All Visits During the Respective Audit Periods

	No. of Referrals		P*
	Before Audit (n=30) (Total Visits=81)	After Audit (n=45) (Total Visits=107)	
Diabetes nurse practitioner	7	9	.999
Dietitian	5	9	.592
Diabetes social worker	7	11	.805
Child psychiatrist	5	3	.294
Diabetes clinic (Endocrinologist)	2	2	.999

*Significance was measured using Fisher's Exact Test.

measurement was plotted at nearly every visit. However, glycosylated hemoglobin levels were measured only 40% of the time, and height was plotted even less often. For yearly actions, cholesterol levels were usually appropriately measured, but other actions were not taken up to 50% of the time. After introduction of the encounter form, no improvement occurred. In fact, the frequency with which blood pressure values were obtained and cholesterol levels measured actually decreased. While our sample size was small, there were no differences in behaviors among first-, second-, or third-year residents. Mean glycosylated hemoglobin level was 12.2% at baseline and 11.5% after

introduction of the encounter form (not significant). Table 2 indicates the number of documented referrals to diabetes team members. Although no specific guidelines are given, the level of the patient's metabolic control indicated by glycosylated hemoglobin values indicates a need for more intervention than was documented. No significant increase in referrals occurred after the introduction of the form.

COMMENT

Baseline chart audits of pediatric residents' care of children with IDDM revealed shortfalls in preferred diabetes care. Based on recommendations provided to the residents, urine protein

was measured 50% of the time, ophthalmology referrals occurred 60% of the time, serum thyroxine was measured 66.7% of the time, blood pressure was measured 66% of the time, height was plotted 23% of the time, and glycosylated hemoglobin was measured 40% of the time.

Documented referrals to the multidisciplinary diabetes team members were also minimal considering the level of metabolic control exhibited by the patients. Residents in our program are exposed to a set of educational interventions that are at least as and perhaps more comprehensive than the IDDM training in many general pediatric programs.² We, therefore, feel that our resident sample was representative of trainees across the country. Thus, these baseline data indicate a need for improved instruction of pediatric residents.

The introduction of a structured visit encounter form is potentially a minimally intrusive, cost-effective mechanism that would serve to remind pediatric residents about needed care. The availability and presence of the structured visit encounter form, however, did not lead to improved diabetes care. Chart audits undertaken after the intervention revealed no improvements in reported referrals and preferred tests. Indeed, evidence was found of possible decay in quality on two measures.

It is possible that the pediatric residents did, in fact, engage in the desired behaviors but failed to record the information in patients' charts. Because the charts were searched for the presence of laboratory reports even when a request was not recorded, and no significant discrepancy was found, this seems unlikely. Furthermore, other studies^{13,14} have demonstrated a high degree of correspondence between actual care and care as recorded in charts.

The reason that availability of a structured encounter form reminder system did not improve pediatric residents' care behaviors is not altogether clear when looking at the success of other seemingly similar interventions⁶⁻⁸; however, it may be due in part to several differences between the interventions. Ertel and Ertel⁸ observed increased compliance with American Academy of Pediatrics' guidelines for physician care

activities and data recording with the use of a structured, age-oriented patient encounter form. The introduction of this form, however, was paired with a tape recording of the patient-physician visit. Although our residents were informed at the beginning of the study that medical record audits of the charts of their patients with IDDM would be performed, with the exception of the presence of the encounter form in the chart, no ongoing reminders were present. Resident care behaviors also improved after the introduction of a computerized medical records reminder system.^{6,7} The computer reminder system also differed in several important ways from our intervention. The computerized system provided the resident with test results from the patient's previous visit and indicated appropriate action to be taken. Our form contained a space on the first page for laboratory results from the previous visit, but the resident was responsible for retrieving and recording these laboratory values from elsewhere in the chart or from the laboratory. The computerized system indicated whether a laboratory result recommended at a certain interval was due to be obtained. The encounter form indicated the frequency with which laboratory results should be obtained; however, it did not provide the resident with the date the laboratory results were previously obtained.

Operational barriers may partially explain why there was not an increase in the number of referrals to diabetes team members.¹⁶ Members could be called at the time of the clinic visit for a consultation but might not be immediately available. If so, the patient had to schedule an appointment at another time. Although similar to what would happen in most practice settings, it is inconvenient for the patient, takes extra time and effort from the resident, and therefore becomes a barrier to referral. In the same fashion, an alteration of the operational setting probably leads to diminished compliance with recording blood pressures. Before the introduction of the structured encounter form,

nurses were responsible for measuring and recording blood pressures. After introduction of the form, nurses were instructed to allow the resident to complete the form. It is possible that nurses assumed that the residents were measuring and recording blood pressure while residents assumed nurses did so. It is important to note that although blood pressure was not measured half of the time, residents failed to follow up on this despite the increased risk of cardiovascular and renal complications associated with diabetes.

We are currently evaluating a more intensive intervention to address the following issue: specifically, implementation of a clinic system that facilitates interaction with a diabetes nurse educator, diabetes social worker, and dietician in the ongoing care of patients. The intent is to provide a care environment in which operational barriers are addressed and minimized.

Finally, caution must be exercised in concluding that failure of pediatric residents to engage in these processes results in poorer metabolic control of the patients.^{16,17} Process variables (laboratory tests ordered, referrals, etc) are important only inasmuch as they lead to adjustment of the treatment regimen. Factors other than physician care, including patient behaviors and the patients' psychosocial environment, contribute to quality of metabolic control.

In summary, our findings indicate that general pediatric residents in their continuity clinics do not demonstrate recommended IDDM care behaviors. The introduction of a reminder system in the form of a visit encounter form to be used at each visit did not increase the frequency of recommended behaviors. In view of the vast participation by general pediatricians in the care of children with IDDM, new training approaches that prepare general pediatricians to provide excellent care for children with IDDM are indicated.

**Ryan's
running,
thanks to a
miracle!**

Ten-year-old Ryan Shewell contracted pneumococcus septicemia at age 9. Upon admission to Children's Hospital and Medical Center in Seattle, physicians discovered that Ryan was born without a spleen. Debridement surgeries saved Ryan's life... but both legs were amputated below the knee. Today, with prostheses and physical therapy, Ryan is back to playing soccer with his friends. His family gives thanks to Ryan's unfailing spirit... and to the hospital, funded in part by Children's Miracle Network.

The Children's Miracle Network Telethon is the one national fundraising appeal specifically for hospitals for children throughout the United States and Canada. In 1988, the telethon raised over \$60 million, making it the largest telethon.

One hundred percent of the money raised goes directly to individual hospitals for children... so that miracles like Ryan's can happen for the 5,000,000 children treated each year.

Alupent[®] Syrup

(metaproterenol sulfate)

Bronchodilator

Tablets	Inhalation Aerosol	Syrup	Inhalation Solution	Inhalation Solution
10 and 20 mg	10 mL	10 mg/5 mL	5%	Unit-dose
				Vials 0.4% and 0.6%

Brief Summary of Prescribing Information

CONTRAINDICATIONS Use in patients with cardiac arrhythmias associated with tachycardia is contraindicated.

Although rare, immediate hypersensitivity reactions can occur. Therefore, Alupent[®] (metaproterenol sulfate USP) is contraindicated in patients with a history of hypersensitivity to any of its components.

WARNINGS Excessive use of adrenergic aerosols is potentially dangerous. Fatalities have been reported following excessive use of Alupent[®] (metaproterenol sulfate USP) as with other sympathomimetic inhalation preparations, and the exact cause is unknown. Cardiac arrest was noted in several cases.

Alupent, like other beta adrenergic agonists, can produce a significant cardiovascular effect in some patients, as measured by pulse rate, blood pressure, symptoms, and/or ECG changes. As with other beta adrenergic aerosols, Alupent can produce paradoxical bronchospasm (which can be life threatening). If it occurs, the preparation should be discontinued immediately and alternative therapy instituted.

Alupent[®] (metaproterenol sulfate USP) should not be used more often than prescribed. Patients should be advised to contact their physician in the event that they do not respond to their usual dose of a sympathomimetic amine aerosol.

PRECAUTIONS General: Extreme care must be exercised with respect to the administration of additional sympathomimetic agents.

Since metaproterenol is a sympathomimetic amine, it should be used with caution in patients with cardiovascular disorders, including ischemic heart disease, hypertension or cardiac arrhythmias, in patients with hyperthyroidism or diabetes mellitus, and in patients who are unusually responsive to sympathomimetic amines or who have convulsive disorders. Significant changes in systolic and diastolic blood pressure could be expected to occur in some patients after use of any beta adrenergic bronchodilator.

Information for Patients: Extreme care must be exercised with respect to the administration of additional sympathomimetic agents. A sufficient interval of time should elapse prior to administration of another sympathomimetic agent.

Drug Interactions: Other beta adrenergic aerosol bronchodilators should not be used concomitantly with Alupent because they may have additive effects. Beta adrenergic agonists should be administered with caution to patients being treated with monoamine oxidase inhibitors or tricyclic antidepressants, since the action of beta adrenergic agonists on the vascular system may be potentiated.

Carcinogenesis/Mutagenesis/Impairment of Fertility: In an 18-month study in mice, Alupent produced an increase in benign ovarian tumors in females at doses corresponding to 320 and 640 times the maximum recommended dose (based on a 50 kg individual). In a two-year study in rats, a non-significant incidence of benign leiomyomas of the mesovarium was noted at 640 times the maximum recommended dose. The relevance of these findings to man is not known. Mutagenic studies with Alupent have not been conducted. Reproduction studies in rats revealed no evidence of impaired fertility.

Pregnancy Teratogenic Effects: Pregnancy Category C: Alupent[®] (metaproterenol sulfate USP) has been shown to be teratogenic and embryotoxic in rabbits when given orally in doses 620 times the human inhalation dose and 62 times the human oral dose. There are no adequate and well-controlled studies in pregnant women. Alupent should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Oral reproduction studies in mice, rats and rabbits showed no teratogenic or embryocidal effects at 50 mg/kg, corresponding to 310 times the human inhalation dose and 31 times the human oral dose. Teratogenic effects in the rabbit included skeletal abnormalities and hydrocephalus with bone separation.

Nursing Mothers: It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Alupent[®] (metaproterenol sulfate USP) is administered to a nursing woman.

Pediatric Use Consult package insert for age limit.

ADVERSE REACTIONS Adverse reactions are similar to those noted with other sympathomimetic agents. Adverse reactions such as tachycardia, hypertension, palpitations, nervousness, tremor, nausea and vomiting have been reported.

The most frequent adverse reaction to Alupent[®] (metaproterenol sulfate USP) administered by metered-dose inhaler among 251 patients in 90-day controlled clinical trials was nervousness. This was reported in 6.8% of patients. Less frequent adverse experiences, occurring in 1-4% of patients were headache, dizziness, palpitations, gastrointestinal distress, tremor, throat irritation, nausea, vomiting, cough and asthma exacerbation. Tachycardia occurred in less than 1% of patients.

HOW SUPPLIED Inhalation Aerosol: Each Alupent[®] Inhalation Aerosol contains 150 mg of metaproterenol sulfate as a micronized powder in inert propellants. Each metered dose delivers through the mouthpiece 0.65 mg metaproterenol sulfate (each mL contains 15 mg). Alupent Inhalation Aerosol with Mouthpiece (NDC 0597-0070-17), net contents 14g (10mL), equipped with blue protective cap. Alupent Inhalation Aerosol Refill (NDC 0597-0070-18), net contents 14g (10 mL).

Store between 59°F (15°C) and 77°F (25°C). Avoid excessive humidity.

Inhalation Solution: Alupent Inhalation Solution is supplied as a 5% solution in bottles of 10 mL or 30 mL with accompanying calibrated dropper. Store below 77°F (25°C). Protect from light. Do not use the solution if it is brown or has a precipitate.

Alupent Inhalation Solution Unit-dose Vial is supplied as a 0.4% or 0.6% clear colorless or nearly colorless solution containing 2.5 mL, with 25 vials per box. Store below 77°F (25°C). Protect from light. Do not use the solution if it is brown or has a precipitate.

Syrup: Alupent is available as a cherry-flavored syrup, 10 mg per teaspoonful (5 mL), in 16 fl. oz. bottles. Store below 86°F (30°C). Protect from light.

Tablets: Alupent is supplied in two dosage strengths as scored, round white tablets in bottles of 100. Tablets of 10 mg coded BI/74. Tablets of 20 mg coded BI/72.

Storage for bottles: Store below 86°F (30°C). Protect from light.

Storage for blister samples: Store below 77°F (25°C). Protect from light.

Consult package insert before prescribing.

Reye's Syndrome

A Reappraisal of Diagnosis in 49 Presumptive Cases

Marie Gauthier, MD; Joanne Guay, MD; Jacques Lacroix, MD; Anne Lortie, MD

• We retrospectively studied 49 patients who were discharged from Sainte-Justine Hospital, Montreal, Canada, or who died between 1970 and 1987 with a presumptive diagnosis of Reye's syndrome. Reye's syndrome was defined as certain, probable, unlikely, or excluded according to clinical, biological, and histologic criteria agreed on a priori by a panel of experts. Patient charts were reviewed blindly by three clinicians. Assessments were similar in 42 cases (86%) (weighted $\kappa = 0.78$ to 0.85 , which suggested substantial agreement); for the remainder, agreement was reached after discussion. Reye's syndrome was considered certain in 1 case (2%), probable in 11 (22%), unlikely in 21 (43%), and excluded in 15 (31%). Four children in the study group did not undergo biopsy or autopsy; in three of these, Reye's syndrome was unlikely according to clinical and biological criteria, and in one, the diagnosis was unclassifiable. The incidence of certain or probable Reye's syndrome was low in our institution during the study period. Our results suggest that the apparent disappearance of Reye's syndrome should be reassessed.

(*AJDC*. 1989;143:1181-1185)

Since its description in 1963,^{1,2} Reye's syndrome (RS) has gained wide acceptance as a distinct clinical and pathologic entity. Despite heightened awareness of the existence of this illness, there has recently been a significant decrease in the reported incidence of RS in the United States,³ as well as in Europe⁴ and Australia.⁵ Between January 1985 and May 1986, a prospective study on

the possible relation between RS and medication was performed in the United States, involving 70 pediatric tertiary care centers.⁶ During a period of 18 months, only 27 cases of RS were identified. In recent years, it appears that RS has become a rare disease.

Considering the significant mortality rate associated with RS,^{7,8} this apparently decreasing incidence is particularly interesting to study. To explain why this is occurring, it would help to understand the cause of RS, which is still unknown; it may also help epidemiologists to predict resurgences and perhaps aid physicians in preventing future cases of this disease.

Arrowsmith et al⁹ reported that aspirin use in children and the incidence of RS decreased quite similarly in the United States from 1980 to 1985. This supported the hypothesis that aspirin exposure was a risk factor in the pathogenesis of RS. However, during the same period, the differential diagnosis of RS became broader, as new infections and metabolic diseases mimicking RS were described in the literature.¹⁰⁻¹⁷ It is hypothesized that some acute encephalopathies identified as RS a decade ago would now be diagnosed differently, thus potentially modifying the past incidence of RS. To test this hypothesis, we retrospectively studied the records of patients diagnosed as having RS in our institution since 1970.

PATIENTS AND METHODS

Sainte-Justine Hospital, Montreal, Canada, is a tertiary care pediatric hospital with over 500 pediatric beds, and is staffed by University of Montreal faculty and residents. The charts of all children discharged from Sainte-Justine Hospital after a first episode of RS, or who died with this presumptive diagnosis, between January 1, 1970, and December 31, 1987, were reviewed. Patients

were excluded if transferred to our institution from any other hospital more than 48 hours after their initial admission.

The data collected included age, sex, clinical history before admission, initial assessment (blood pressure, state of consciousness, and response to painful stimuli), laboratory data on admission (creatinine level, cerebrospinal fluid cytologic measurements, and biochemical data) and during the first 48 hours after admission (aspartate aminotransferase, alanine aminotransferase, and ammonia levels), peak bilirubin level during their clinical course, urinary organic acid and serum carnitine levels, results of light and electron microscopy of the liver (when available), and results of the autopsy, when performed.

Clinical Staging

Patients were classified retrospectively according to neurologic assessment on admission. A six-level staging system was used¹⁸: stage 0, alert, wakeful; stage I, difficult to arouse, lethargic, and sleepy; stage II, delirious, combative; stage III, unarousable, predominantly flexor motor responses, or decorticate; stage IV, unarousable, decerebrate; and stage V, unarousable, flaccid paralysis, areflexia, and unresponsive pupils.

Case Definition

Initially, we consulted four experts, including a pediatric gastroenterologist, a pediatric neurologist, a pediatrician with at least 10 years of experience in the care of critically ill children, and a geneticist. They were asked to choose from a list of clinical, biological, and histologic criteria—the criteria that they would use at the time of the study to classify a presumptive case of RS as certain, probable, unlikely, or excluded. They were also asked to give differential criteria for patients younger or older than 12 months of age, and to suggest other criteria if the list was judged incomplete. Second, we summarized the various opinions of the experts, and finally established the definitions described below. There was a consensus of opinion on the final definitions by all experts.

A presumptive case was classified as certain or probable according to criteria listed in

Accepted for publication March 20, 1989.

Table 1.—Diagnostic Criteria Used to Classify a Presumptive Case of Reye's Syndrome as Certain or Probable*

	Certain		Probable	
	Age ≥12 mo	Age <12 mo	Age ≥12 mo	Age <12 mo
Clinical history				
Consistent with Reye's syndrome	+	—	+	—
Increased AST/ALT levels	+	+	+	+
Increased ammonia level	+	+	+	+
Threefold or greater rise in AST/ALT or ammonia levels	+	+	+	+
Total bilirubin level <51 μmol/L	+	+	+	+
Organic acid levels compatible with Reye's syndrome	—	+	—	—
Normal serum carnitine level	—	+	—	—
No other obvious explanation for the acute illness	+	+	+	+
Hepatic steatosis	+	+	+	+
Mitochondrial alterations compatible with Reye's syndrome	+	+	—	—

*Plus sign indicates that criterion must be present; minus sign, that criterion may be found but is not essential for diagnosis; AST, aspartate aminotransferase; and ALT, alanine aminotransferase.

Table 1. The clinical history was considered compatible with RS if prodromal illness (only required if stage 0 or I) was followed by protracted vomiting with or without progressive alteration of consciousness. In a child less than 12 months of age, the criteria differed compared with older children: a clinical history consistent with RS was not required, and for cases classified as certain, urinary organic acid levels had to be compatible with RS,¹⁹ and serum carnitine level had to be normal.

The occurrence of RS was considered unlikely (1) if two or more of a list of eight characteristics were present (Table 2) (myocardial damage had to be documented by altered contractility, echocardiography, or cardiogenic shock; shock on admission was defined as arterial hypotension with systolic blood pressure at least 30 mm Hg lower than normal) or (2) if the RS was not certain, probable, or excluded. Reye's syndrome was excluded if one of the findings defined in Table 2 was present.

Chart Review

All charts were analyzed independently by three of us, two pediatric intensivists (M.G., J.G.) and a neurology fellow (A.L.). Results were combined from this parallel study. If the reviewers disagreed, a consensus was reached after discussion.

For statistical purposes, we quantified the degree of agreement achieved in the ratings of RS. The concordance of the different raters was expressed in two ways. First, the number of exact agreements for diagnostic categories was noted and cited as a percentage agreement score among the cases stud-

ied. Second, a weighted κ was calculated using the method reported by Kramer and Feinstein.²² This score indicates interobserver agreement with ordinal data. Disagreements were weighted as 1 for a disagreement of one categorical rank, 2 for two ranks, and 3 for three ranks. The strength of interobserver agreement was considered greater than that expected by chance if the value of the weighted κ was higher than the quantitatively significant level of +0.5. To test the null hypothesis that weighted $\kappa = 0$, we calculated an SEM, providing that the total number of cases was greater than $2g^2$, where g is the number of categories; this SEM was used to compute P values to test the null hypothesis. A $P < .05$ (one-tailed test) suggests that the agreement could not be expected by chance only.

RESULTS

Fifty-three patients were diagnosed as having first episodes of RS, either at discharge from the hospital or as cause of death during the 18-year period studied. Four were excluded before analysis because they were transferred to our hospital from 2 to 21 days after admission to a first hospital.

Of the 49 presumptive cases of RS studied, 47% (23/49) of the patients were younger than 12 months at the time of presentation, 25% (12/49) were between 1 and 4 years of age, 18% (9/49) were between 5 and 9 years of age, and 10% (5/49) were between 10 and 14 years of age (Fig 1). The mean age was

Table 2.—Diagnostic Criteria Used to Classify a Presumptive Case of Reye's Syndrome as Unlikely or Excluded*

Reye's syndrome was considered unlikely if the case was not already classified as certain, probable, or excluded, or if two or more of the following characteristics were present:

1. Total bilirubin level ≥ 51 μmol/L
2. Normal ammonia level (if stage 2 or beyond)
3. A threefold or greater rise in creatinine level
4. Focal neurological signs
5. Myocardial damage
6. No prodromal illness (if ≥ 12 months of age)
7. Shock on admission
8. CSF protein level >0.5 g/L

Reye's syndrome was considered excluded if one of the following characteristics was present:

1. Normal AST/ALT²⁰
2. Necrosis and inflammation on liver biopsy²⁰
3. No steatosis²⁰
4. No significant mitochondrial alterations on electron microscopy²¹
5. $>2.5 \times 10^9$ /L
6. Other identified cause for the acute illness

*CSF indicates cerebrospinal fluid; AST, aspartate aminotransferase; and ALT, alanine aminotransferase.

Fig 1.—Distribution of cases of Reye's syndrome at Sainte-Justine Hospital, Montreal, Canada, according to age.

3.2 years (range, 1 month to 13 years 1 month; median, 19 months). The sex proportion was 71% boys and 29% girls. Two percent (1/49) were classified on admission as having stage 0 disease, 25% (12/49) as stage I, 20% (10/49) as stages II and III, 27% (13/49) as stage IV, and 6% (3/49) as stage V. Thirty-three percent (16/49) of the children died during their hospitalization.

Histologic reports were available in 92% (45/49) of patients. Ninety-one per-

Table 3.—Certitude of Diagnosis in 49 Presumed Cases of Reye's Syndrome

	Classification at First Attempt	Classification After Discussion	Total (%)
Certain	...	1	1 (2)
Probable	8	3	11 (22)
Unlikely	20	1	21 (43)
Excluded	14	1	15 (31)
Unclassified	...	1	1 (2)

Fig 2.—Incidence of Reye's syndrome at Sainte-Justine Hospital, Montreal, Canada, from 1970 to 1987.

cent (41/47) of these patients had a liver biopsy performed soon after admission, and in 9% (4/45), histologic specimens were taken only at autopsy. Electron microscopy was available for three cases; one of these studies showed typical mitochondrial alterations, the second one showed minimal mitochondrial swelling, the endoplasmic reticulum being the most altered, and the last did not reveal any mitochondrial abnormality.

All three of the reviewers agreed in 12 (86%) of the 49 cases (86% is thus the percentage agreement score). Two disagreements exceeded one category of rank. Three comparisons were performed between the three observers, as suggested by Kramer and Feinstein.²² The weighted κ was higher than the quantitatively significant level of +0.5 or all three comparisons (weighted $\kappa = 0.78, 0.85, \text{ and } 0.83$). The z scores were 5.57, 5.75, and 7.5 ($P < .00003$ in each instance), which again suggested

that the agreements could not be expected by chance alone. These results validate the procedure, because classifying the cases in four categories seems to be reproducible and stochastically significant.

Table 3 shows the results of the parallel diagnostic classification done by three of us. Twelve patients were classified as having certain ($n = 1$) and probable ($n = 11$) RS. They were significantly older, compared with the rest of the group (Fig 1) (mean age, 6.1 years; range, 3 months to 12 years 7 months) vs 2.2 years (range, 2 months to 13 years 1 month) ($P < .001$). Two of these 12 patients were less than 12 months of age at the time of diagnosis, while 21 of the 37 other children studied were in this age group (17% vs 57%, $P < .05$).

Twenty-one presumptive cases (43%) were considered unlikely. In five, the charts were not classifiable either as certain, probable, or excluded; there-

fore, they were categorized as unlikely. Most cases (16 of 21) were classified as unlikely because two or more of the following characteristics were found: shock on admission (8 of 16), cerebrospinal fluid protein level greater than 0.5 g/L (13 of 16), a threefold or greater rise in creatinine level on admission (4 of 16), no prodromal illness in patients older than 12 months (1 of 16), and total bilirubin level of 51 $\mu\text{mol/L}$ (1 of 16). In 9 of the 21 cases classified as unlikely, an alternative diagnosis appeared more likely: viral encephalitis (4 of 21), septic shock (3 of 21), and hypovolemic shock due to gastroenteritis (2 of 21).

In 15 presumptive cases, a diagnosis of RS was excluded. In 11, the final histologic report was not compatible with RS: hepatic tissue necrosis on light microscopy was seen in 6, hepatic inflammation in 2, no significant mitochondrial alterations on electron microscopy in 2, and absence of hepatic steatosis in 1. In all these cases except 1, nothing other than hepatic steatosis was mentioned on the preliminary pathologic reports; final interpretations were sent directly to the charts several days or weeks after the acute disease, almost always after discharge or death of the patients. We considered these 11 cases in retrospect to be drug-induced hepatitis in 1, hepatitis of unknown cause in 1, septic shock in 2, probable adenovirus type 3 systemic infection in 1, severe gastroenteritis with hypovolemic shock in 1, acyl-CoA dehydrogenase deficiency (identified after recurrences) in 2, and acute illnesses of unknown cause in 2. For the last 4 cases excluded, reasons for the exclusion were as follows: proved adenovirus type 7 multisystemic infection, aseptic meningitis, cerebral astrocytoma found at autopsy in a patient who was brain dead on admission, and head trauma in a battered child. Of the 4 children in whom biopsies or autopsies were not performed, 3 were classified as unlikely RS according to clinical and biological criteria, and 1 was judged unclassifiable (Table 3).

The reasons for disagreement among observers were as follows: in three patients, the clinical history was judged compatible with RS by one or two of the observers and not compatible by the other(s); after discussion, these cases were classified as certain in one patient and unlikely in two. One case was

thought to be caused by dimenhydrinate poisoning by one of the observers but was classified as probable after discussion. Another was judged to be an adenovirus type 7 multisystemic infection by one observer. However, the two other observers had not considered this possibility: this case was classified as excluded. Finally, one case was categorized as unclassifiable because of insufficient information (no liver biopsy, spinal tap, or brain biopsy was performed).

Figure 2 shows the incidence of RS in our institution since 1970. Of the 12 patients classified as certain or probable, 6 were admitted during the first 6 years of the study (1970 to 1975), 4 were treated from 1976 to 1981, and 2 were diagnosed over the last 6 years (1982 to 1987). The incidence of these cases remained low during the 18 years of the study.

COMMENT

Of the 49 presumptive cases studied, only 24% (12/49) were considered certain or probable. Because criteria used to classify a case as certain were rather strict, a very small number of certain cases of RS was expected. However, we were surprised by the large number of cases classified as unlikely (43%) or excluded (31%). These results merit several comments concerning the definitions described above; the age of patients involved; the way RS was diagnosed by clinicians of our institution during the study period; and why the most astute clinician had, until recently, several reasons to overdiagnose RS.

One may allege that the criteria used to classify a case as probable RS were too strict, or that those rendering RS unlikely or excluded were too broad. We do not think this was the case, even though we do not have the pretention to propose them as the "gold standard" for diagnosis of RS. The necessity for every child with a possibility of RS to undergo biopsy was debatable in the 1970s and could still be so today. Nonetheless, in our hospital where 92% of the patients with presumptive cases of RS underwent biopsy or autopsy, we considered hepatic steatosis essential for a diagnosis of RS to be probable. Moreover, this large percentage of cases with histologic documentation, one of the highest ever reported in a series of RS (vs 30% to 40%^{6,23,24}), validates our conclusions.

The category "unlikely" was the most difficult to define. As already described, two or more of a list of eight characteristics were required. Even if several of these findings could have been considered sufficient by themselves to render a presumptive case unlikely, a more restrictive definition was preferred. The absence of a prodromal illness in children 12 months of age or more was one of these required findings. Indeed, in approximately 90% of the cases reported by the Centers for Disease Control, Atlanta, a prodromal illness occurred,²⁴ the absence of previous infection being more suggestive of metabolic disease rather than RS.²⁵ Bilirubin concentrations are characteristically normal or minimally elevated in RS.²⁰ Hyperammonemia has been observed in almost all patients early in the course of the illness,²⁰ except in grade I where ammonia levels are often normal.²⁶ Renal abnormalities are usually not severe in RS and typically consist of elevations in blood urea nitrogen concentrations; occasional cases of transient acute renal failure have been reported,^{27,28} but in some of these, central lobular necrosis was found on liver biopsy, rendering the diagnosis of RS doubtful.

Reye's syndrome may cause progressive cerebral herniation, with a rostro-caudal progression but no focal signs.²⁰ Even if the heart shows evidence of lipid accumulation, cardiac manifestations are extremely rare and have not been mentioned in recent reviews on RS.^{20,29} Signs of shock could be secondary to cerebral death or to hypovolemia, but are so unusual that they are omitted in descriptions of the clinical spectrum of the disease.^{20,29} Prolonged seizures can be associated with elevated cerebrospinal fluid protein levels because of a transient breakdown of the blood-brain barrier; in the majority of cases, however, cerebrospinal fluid protein levels remain below 0.5 g/L.³⁰ If present in a patient without seizures, elevated cerebrospinal fluid protein level would more likely suggest central nervous system infection.

Age distribution for our group of 49 patients (median age, 19 months) was similar to the original description of the disease by Reye et al¹ and to other series of sporadic cases of RS from Australia,⁵ Ireland,³¹ and England.³² Although

cases classified as excluded and unlikely RS were encountered in all age groups in our series (Fig 1), these patients were significantly younger compared with the total group of patients. This is not surprising considering that it may be particularly difficult in young children to differentiate RS from anoxic encephalopathy, inborn errors of metabolism, or other conditions.^{33,34}

Our study relates the experience of a large tertiary care pediatric hospital, staffed with a very active gastroenterology team, which has already proved its scientific interest in RS.³⁵ Over the years, this team has used the criteria proposed by the Centers for Disease Control, to diagnose RS. These criteria are very broad and nonrestrictive,^{3,18,24} which obviously allows overdiagnosis. Pathological confirmation is not required; an alteration in the level of consciousness with elevated transaminase or ammonia levels are enough to diagnose RS, even in comatose children. This is not specific enough to exclude clinically similar disorders.³⁶ These flaws in diagnostic criteria are so apparent that the Centers for Disease Control have recently drawn attention to the nonspecificity of the case definition and have suggested that it should be more rigorous.³⁴

During the 1970s, many publications from different sources emphasized the importance of recognizing RS early in children with acute alteration of consciousness. At the same time, the differential diagnosis of RS was rather limited, compared with what it is today. More recently, an extensive list of disorders mimicking RS have been described.^{11,12-16,37,38} Moreover, fatty metamorphosis of the liver was often used as an essential criterion for establishing a diagnosis of RS, until it was shown to be present in disorders of fatty acid oxidation and in defects of ureagenesis,^{16,39} and ubiquitous in children dying of a traumatic death or of a sudden unexpected natural death.⁴⁰

Because of all these considerations, the most astute and competent clinician had, until recently, many reasons to overdiagnose and overreport RS.

Broadening of the differential diagnosis of RS has not only served to establish an exhaustive list of RS mimickers but has rendered the clinician much more

circumspect today with a presumed case of RS. For clinicians, RS has become a diagnosis of exclusion. Obviously, acute encephalopathies misdiagnosed as RS in the past were not necessarily all genetic diseases or adenovirus type 7 infections. As reported by Hurwitz et al⁶ and in the present study, viral hepatitis, viral encephalitis, hypovolemic shock, etc. were often mistaken for RS. This happened because of different factors, such as fear among physicians of missing such a severe and treatable disease and their great and sometimes exaggerated enthusiasm toward this newly described entity. We agree entirely with Rowe et

al³⁶ that if inherited defects had been responsible for the majority of cases of RS in the past, the recent reduction in incidence would have to imply an implausibly large genetic shift in the population.

This change in the physician's perception of this disease coincides with the decreasing trend observed in the incidence of RS. A cause-effect relationship between both factors is hard to prove scientifically, since, by definition, a change of attitude is a subjective phenomenon. However, our results suggest that this possibility must be taken into account, as is the link between the decreasing trend of RS and aspirin use.

We have shown that the true incidence of RS has always been low in our institution since 1970. It is not possible, at this point, to generalize our data to other centers. However, our results indicate that the diagnostic criteria of RS should be reassessed by the Centers for Disease Control and that the apparent disappearance of RS must be reevaluated. Although it might appear to be a disturbing question, one must try to discover if this disappearance is a fact or a fancy.

We thank Nancy Haley, Marie Lambert, Albert Larbrisseau, Andrée M. Weber, and Michel Weber for their help, and Silvia Manara for her expert secretarial work.

Neurologic Status and Intracranial Hemorrhage in Very-Low-Birth-Weight Preterm Infants

Outcome at 1 Year and 5 Years

Lisa M. Ford, MD; Jean Steichen, MD; Paula A. Steichen Asch, PhD; Diane Babcock, MD; M. H. Fogelson, MD

• Twenty-six very-low-birth-weight preterm infants with and without intracranial hemorrhage (ICH) were followed up prospectively from birth to school age to determine the relationship between ICH and subsequent neurologic and cognitive outcomes. All children had sequential cranial ultrasound examinations at birth and neurologic assessments at 3-month intervals during the first year, at 1 year of age, and at 5 to 6 years; psychometric assessments were done at 5 to 6 years. Seventeen children had no ICH, 3 had grade 1 ICH, 1 had grade 3 ICH, and 5 had grade 4 ICH. The 1-year Amiel-Tison neurologic assessment in 25 infants demonstrated that 14 were normal, 3 were suspect, and 8 were abnormal. By 5 to 6 years of age, 5 of 8 children neurologically abnormal at 1 year remained abnormal, 2 of 3 children neurologically suspect at 1 year remained suspect; while 9 of 15 children neurologically normal at 1 year remained normal,

the remaining 6 had become suspect. The predominant neurologic abnormality at 5 to 6 years was subtle neurologic dysfunctioning. The Wechsler Preschool and Primary Scale of Intelligence at 5 to 6 years revealed a mean group IQ score of 92.1. The Beery Visual Motor Integration Test results demonstrated that 18 of 26 children had mild to severe visual motor perceptual difficulties. Severe ICH (grades 3 and 4) correlated with abnormal neurologic performances at 1 and 5 to 6 years. Mild ICH (grade 1) and no ICH did not correlate with any one of the 1-year neurologic classifications. The 1-year status correlated with the 5- to 6-year neurologic outcome best for children who were either neurologically suspect or abnormal at age 1 year. The 1-year neurologic score did not correlate with 5- to 6-year IQ and Beery Visual Motor Integration Test scores.

(AJDC. 1989;143:1186-1190)

More recent studies of long-term outcomes in school-age children demonstrate that survivors of severe ICH remain abnormal.¹⁷ Some studies have reported that survivors of mild ICH may display a variety of subtle neurologic and cognitive dysfunction, including motor incoordination, hyperactivity, attention and learning deficits, and visual motor difficulties.^{18,17,18} However, more studies are needed to determine the exact extent of long-term sequelae associated with mild or asymptomatic ICH. Since 1980, the availability of cranial ultrasound has allowed accurate diagnosis of all grades of ICH, thus enabling physicians to correlate accurately ICH severity with outcome measures.

PURPOSE AND HYPOTHESIS

The purpose of this study was to determine and relate neurologic and cognitive outcomes in school-age children who had ICH with their 1-year neurologic results. The study objectives were to establish (1) whether an association exists between ICH severity and outcome at school age; (2) whether the 1-year neurologic status is an accurate predictor of school-age function; and (3) more specifically, whether transient and/or persistent neurologic abnormalities present during the first year are markers for later neurodevelopmental and cognitive disabilities.

We hypothesized that (1) severe ICH is associated with early and later childhood neurologic sequelae; (2) first-year neurologic status is a predictor of later neurologic functioning; and (3) transient and persistent neurologic abnormalities during the first postnatal year are indicators of later neurologic abnormalities.

Intracranial hemorrhage (ICH) is a common and clinically serious complication in the very-low-birth-weight preterm infant.^{1,2} The overall occurrence rate was reported to range between 40% and 60% from 1980 through 1985; after 1986, incidences were reported to be 13% to 48%.³⁻⁶ Intracranial hemorrhage is associated with an increased mortality rate and risk for serious neu-

rologic sequelae.¹ The incidence of major neurologic sequelae increases with the severity of hemorrhage and can be associated with posthemorrhagic complications.^{1,4,6,7} Long-term neurologic morbidity observed in some survivors includes hydrocephalus, motor handicaps, and mental retardation,^{8,9} as well as learning and developmental disabilities.^{6,7,10-13}

Initial follow-up studies, which primarily focused on infancy and early childhood outcomes, demonstrated that severe ICH (grades 3 and 4) was associated with significant mental or motor handicaps.^{8,9,14-16} Mild ICH (grades 1 and 2) was often related to transient or subtle neurologic abnormalities present during the first postnatal year, which frequently normalized by the end of the first year of life.^{8,9}

PATIENTS AND METHODS

Patients

Birth to 1 Year.—The study population was derived from an original sample of 64 appropriate-for-gestational-age, very-low-birth-weight (≤ 1500 g), preterm infants studied from August 1979 to December 1980.¹⁹ All were outborn and transferred to Cincinnati (Ohio) Children's Hospital Medical Center Regional Newborn Intensive Care Unit. These infants had the following characteristics: mean birth weight of 1113 g (range, 580 to 1480 g), mean gestational age of 29 weeks (range, 24 to 33 weeks), and mean Apgar scores of 4 at 1 minute and 6 at 5 minutes; there were 33 boys and 31 girls, 10 black and 54 white. The rate of ICH was 54.7% (35/64). The neonatal mortality rate was 46.9% (30/64), leaving 34 infants for potential follow-up study. Among the 30 neonatal deaths, 23 (76.7%) occurred in children with ICH.

Initially, the 34 surviving infants were followed up from birth to 1 year. Their characteristics were not different from the original group of 64 infants, except for a significant difference in sex distribution: 24 were girls and 10 were boys ($P < .05$).

Follow-up at 5 to 6 Years.—At the age of 5 to 6 years, 26 of 34 infants could be located for follow-up assessment. Eight children had been unavailable for follow-up for the following reasons: two had moved more than 320 km from our institution, one family refused follow-up, and five children could not be located. The characteristics of the 26 children were not different from the total sample of 64 infants enrolled at birth or from the group of 34 infants followed up during the first year.

Measures

Birth to 1 Year.—Cranial ultrasonography was performed sequentially on days 1, 4, 7, 13, 21, and 28 of life to document presence or absence of ICH¹⁹; ultrasounds were not evaluated for other lesions. Grades of ICH included 1, subependymal hemorrhage; 2, intraventricular hemorrhage without ventricular distention; 3, intraventricular hemorrhage with ventricular distention; and 4, intraventricular hemorrhage with cerebral parenchymal hemorrhagic involvement.⁴ Patients with periventricular leukodensities were categorized as having grade 4 ICH.

Neurodevelopmental assessments were done at 3, 6, 9, and 12 months' postconceptional age using the Amiel-Tison Neurologic Assessment.²⁰ At the end of the first year, infants were assigned a neurologic score by one of us (J.S.), "blinded," ie, unaware of the initial intraventricular hemorrhage grade. Neurologic classification was as follows: (1) normal, no neurologic abnormalities; (2) suspect, transient neurologic abnormalities that disappeared by the end of the first year; or (3)

abnormal, persistent neurologic abnormalities throughout and at the end of the first year of life. Abnormal neurologic signs included persistent abnormalities of tone (hypertonicity or hypotonicity), abnormal persistence of primitive reflexes, abnormal eye movements, abnormal levels of arousal and consciousness, and poor head control.

Five to 6 Years.—The 5- to 6-year follow-up assessment consisted of neurologic and psychometric evaluations, performed by examiners different from those involved in the study phase from birth to 1 year. To reduce investigator bias, examiners were blinded, ie, not aware of each child's ICH grade, nursery course, and 1-year neurologic score.

A standard neurologic evaluation was performed by one of us, a pediatric neurologist (L.M.F.), as described by Baird and Gordon.²¹ Three neurologic classifications were used: (1) normal, no neurologic abnormalities; (2) suspect, fine- or gross-motor deficit, attention-deficit disorders, or language inefficiency; and (3) abnormal, static neuromotor deficits, including hemiparesis, quadriplegia, spastic diplegia, blindness, deafness, seizure disorder, or hydrocephalus.

Impairment of fine-motor, gross-motor, or both skills included difficulty with mirror or fine-finger movements, hop and balance on one foot or both feet, or mild hemiatrophies.

Psychometric evaluations measured cognitive functioning using the Wechsler Preschool and Primary Scale of Intelligence (WPPSI) and visual motor perceptual status using the Beery Visual Motor Integration Test (VMI).²² The WPPSI has a full scale and two subscales—verbal and performance. Based on the full-scale scores, three categories were defined as follows: normal, IQ of 85 or higher; borderline, IQ of 71 to 84; and abnormal, IQ of 70 or lower.

The Beery VMI is a form-copying test of 24 geometric forms. Based on raw scores of 0 to 24, age-equivalent percentiles and standard scores were assigned. Standard scores have a mean of 10 and an SD of 3. Children with standard scores of 7 or more had normal age-related visual motor skills, while those with scores of 7 or less had abnormal skills.

Data Analysis

Descriptive statistics and correlation coefficients among variables were obtained. Multivariate regression analysis was performed to examine the combined effect of ICH and other predictors on outcome.

RESULTS

Birth ICH and 1-Year Outcome

The distribution of ICH for the 26 survivors studied was as follows: 17 had no ICH; 3 had grade 1; 1 had grade 3; and 5 had grade 4.

Nineteen children developed transient or persistent ventricular dilatation during the first year; these included 10 children with no ICH and all 9 children with any degree of ICH. Only 7 children, all with no ICH, had no ventriculomegaly. Posthemorrhagic hydrocephalus requiring a ventriculoperitoneal shunt developed in one child with grade 4 ICH.

Twenty-five of 26 children were examined during and at the end of the first year with the Amiel-Tison Neurologic Assessment: 14 were normal, 3 were suspect (ie, demonstrating transient neurologic abnormalities at some point during the first year that had disappeared by the end of the first year), and 8 were abnormal (showing persistent neurologic abnormalities throughout and at the end of the first year). One child who was unavailable for follow-up testing was reported by a community health clinic to have normal neurodevelopmental status during and at the end of the first year.

The ICH grade correlated negatively with a normal 1-year neurologic outcome ($r = -.58$; $P < .001$). The more severe the ICH injury was, the less normal the neurologic performance. As shown in Table 1, five of six infants with grades 3 and 4 ICH were classified as having persistent neurologic abnormalities at the age of 1 year; one child with grade 4 ICH was neurologically normal at 1 year. By contrast, among 20 children with no or mild ICH (grade 0 and 1), 14 were neurologically normal at 1 year, whereas 6 had transient persistent neurologic sequelae.

Birth ICH and 5- to 6-Year Outcome

Neurologic evaluation at 5 to 6 years showed 9 children were normal, 11 were suspect, and 6 were abnormal. The predominant neurologic dysfunctions were subtle motor disabilities consisting of fine-motor or gross-motor incoordination or both. Specific neurologic abnormalities among children with no ICH or grade 1 ICH included sensorineural hearing loss, seizures, and spastic diplegia, whereas children with grades 3 and 4 ICH demonstrated hemiplegia, diplegia, quadriplegia, blindness, and deafness.

The 5- to 6-year psychometric assessments revealed a WPPSI mean full-

scale summary score of 92.1 for all groups combined. Scores were in the normal range in 19 children, borderline in 6 children, and abnormal in only 1 child. The VMI mean standard score was 4.19. The majority of children, 18 of 26, demonstrated dysfunctions on VMI testing; only 8 children had normal visual-motor skills. Furthermore, 21 children demonstrated a variety of additional deficits on psychometric testing; these deficits included speech, hearing, language, and attention problems. In these subjects, future follow-up psychological evaluations were recommended in one or more of these specific areas for adequate school placement.

Severity of ICH did not correlate with 5- to 6-year cognitive functioning on the WPPSI scale ($r = -.17$; not significant [NS]) (Table 2). Among children with grade 4 ICH, two of five had normal full-scale scores; indeed, one of these two children had an exceptional IQ of 127. Among six children with borderline IQ scores, however, three had no ICH.

Similarly, ICH did not correlate with 5-year VMI scores ($r = -.10$; NS). Despite ICH status, 18 children had visual motor perceptual difficulties.

Severity of ICH correlated negatively with 5- to 6-year neurologic outcome ($r = -.41$; $P < .01$). As shown in Table 1, four of six children with severe ICH (grades 3 and 4) were neurologically abnormal at 5 years, one was suspect, and one was normal; whereas among 20 children with no or minimal ICH (grades 0 and 1), 8 were neurologically normal, 10 demonstrated subtle neurologic dysfunction, and only 2 were abnormal.

Relationship Between First-Year and 5- to 6-Year Neurologic Outcomes

The first-year Amiel-Tison Neurologic Assessment score correlated significantly with the 5- to 6-year neurologic assessment ($r = .53$; $P < .01$) (Table 3). Among 11 children who were either abnormal or suspect at 1 year of age, 9 remained suspect or abnormal at 5 to 6 years of age. The remaining 2 of 11 children showed improvement and were neurologically normal at 5 to 6 years. Of 15 children normal at 1 year of age, 9 remained normal, while 6 were now suspect, demonstrating a combination of fine- and gross-motor dysfunction; none was abnormal.

Table 1.—Intracranial Hemorrhage (ICH) Status and 1-Year and 5- to 6-Year Neurologic Outcome							
ICH Grade	Normal		Suspect		Abnormal		n
	At 1 y	At 5-6 y	At 1 y	At 5-6 y	At 1 y	At 5-6 y

1	1	1	1	2	1	0	3
2	0	0	0	0	0	0	0
3	0	0	0	0	1	1	1
4	1	1	0	1	4	3	5
Total	15	9	3	11	8	6	26

*One child was not examined by investigator during the first year. Records from a community health clinic reported normal neurologic status during the first year.

Table 2.—Intracranial Hemorrhage (ICH) Status and Psychometric Scores				
ICH Grade	Verbal IQ	Performance IQ	Full-Scale WPPSI* IQ	VMI Standard Score* IQ
0 (n=17)	≥85 (n=13) 70-80 (n=4)	≥85 (n=13) 70-84 (n=4)	≥85 (n=14) 70-84 (n=3)	≥7 (n=5) <7 (n=12)
1 (n=3)	≥85 (n=3)	≥85 (n=3)	≥85 (n=3)	≥7 (n=2) <7 (n=1)
3 (n=1)	≥85 (n=1)	70-84 (n=1)	70-85 (n=1)	≥7 (n=1)
4 (n=5)	≥85 (n=2) 70-84 (n=2) <70 (n=1)	≥85 (n=2) 70-84 (n=1) <70 (n=1)	≥85 (n=2) 70-84 (n=1) <70 (n=1)	≥7 (n=1) <7 (n=4)

*WPPSI indicates Wechsler Preschool and Primary Scale of Intelligence; VMI, Beery Visual Motor Integration Test.

Table 3.—Relationship of 1-Year and 5- to 6-Year Neurologic Status				
	At 5 to 6 y			Total
	Normal	Suspect	Abnormal	
At 1 y				
Normal	9	6	0	15
Suspect	0	2	1	3
Abnormal	2	1	5	8
Total	11	9	6	26

Five- to 6-year cognitive functioning did not correlate with the 1-year neurologic status. Most children, regardless of their 1-year neurologic status, had normal full-scale IQs at 5 to 6 years. One child with grade 4 ICH and an abnormal 1-year neurologic status had an exceptional 5- to 6-year IQ of 127.

Significant relationships existed between 5- to 6-year neurologic status and WPPSI ($r = .39$; $P < .05$), as well as VMI ($r = .66$; $P < .001$). Thus, at 5 to 6 years, there was a correlation between neurologic and cognitive status.

Multivariate Approach to Predicting 1- and 5- to 6-Year Outcomes in Infants With ICH

Regression Analysis: 1-Year Neurologic Outcome.—One-year neurologic scores in the follow-up sample were predicted by the following variables in descending order of importance: ICH (standardized β [SB] = .52), gestational age (SB = .42), and sex (SB = -.42); birth weight did not add to the prediction (SB = -.06). The amount of variance in the 1-year neurologic performance accounted for by these four

predictors was .57 (multiple r [MR] = -.75).

These results show that ICH is the most relevant factor in the prediction of the 1-year neurologic outcome (25% of the variance) followed by gestational age and sex (32% of the variance).

Regression Analysis: 5- to 6-Year Neurologic Outcome.—The 5- to 6-year neurologic outcome was predicted by the following variables: ICH (SB = .35), gestational age (SB = -.37), birth weight (SB = .06), sex (SB = -.01), and 1-year neurologic performance (SB = .36). The amount of variance accounted for by these variables in the 5- to 6-year neurologic performance was 33% (MR = .57). As expected, the short-range predictor of 1-year neurologic outcomes makes the highest contribution, yet neonatal ICH is not a negligible predictor. Although important, the relative contribution of ICH and gestational age diminished, while that of 1-year neurologic outcome increased.

Similarly, predictions regarding 5- to 6-year WPPSI performance (amount of variance accounted for 13%, MR = .36) and VMI performance (amount of variance accounted for 10%, MR = .32) were low. The importance of ICH as a predictor was reduced (SB = .04).

By contrast, the predictability of the 5- to 6-year neurologic performance was enhanced by considering as predictors the WPPSI (SB = -.16) and VMI (SB = -.30), and the amount of variance increased to 42% (MR = .65).

COMMENT

In this study, ICH severity correlated with the extent of neurologic sequelae seen at early (1-year) and school-age (5- to 6-year) follow-up evaluations. The more severe the ICH, the less normal were neurologic performances. Children with severe ICH (grades 3 and 4) were classified as neurologically suspect or abnormal on early and later neurologic examinations. Mild ICH (grade 1) was associated with all neurologic classifications at 1 year, whereas it was primarily associated with subtle neurologic dysfunctioning (suspect neurologic category) at 5 to 6 years. Thus, ICH is an important variable that influences early and later neurologic outcomes in affected infants.

Our results associating ICH and neurologic outcomes are consistent with previous longitudinal studies of short- and long-term outcomes. In contrast to Palmer et al,²³ we did not find an association between ventriculomegaly and outcome measures. Furthermore, in our study, ICH severity appeared to be an important factor in the development of posthemorrhagic ventricular dilatation, since all children with ICH had persistent ventriculomegaly throughout the first year of life.

The ICH grading system used in 1980 made no distinction between two types of grade 4 ICH lesions, cerebral parenchymal hemorrhage and periventricular leukomalacia. Thus, outcomes were not differentiated between these two lesions. This is an important issue because of controversial aspects pertaining to grade 4 ICH, ie, hemorrhage vs ischemia, their associated pathophysiologic risk factors, and prognostic outcomes. One attractive hypothesis suggests that intracerebral hemorrhage is only a component of a larger lesion, ischemic in nature.²⁴

The absence of ICH did not guarantee a normal neurologic score either at 1 year or 5 to 6 years. Although most children with no ICH were normal on early follow-up evaluation, they primarily demonstrated subtle neuromotor dysfunction at school age. Thus, while ICH is a major factor influencing future neurologic outcome, additional variables also have influence. We postulate that such variables include severity of perinatal medical complications, birth growth parameters (birth weight), and maturation (gestational age). Furthermore, since the correlation between ICH and neurologic status diminishes somewhat with increasing age, postnatal socioeconomic environment is also likely an important variable influencing neurologic outcome. Previous studies have substantiated the importance of such variables on neurologic outcome.¹⁷

Overall, our results indicate that all very-low-birth-weight preterm infants with and without ICH should be monitored throughout early childhood for neurologic sequelae to detect subtle and overt abnormalities requiring special attention.

The 1-year neurologic outcome was the most accurate predictor of the 5- to

6-year neurologic outcomes vs other predictors, including ICH status, birth weight, gestational age, and sex. When specific 1-year neurologic classifications were compared with 5- to 6-year classifications, our findings were slightly different from previous studies. These reports concluded that the best correlations between infancy and school-age neurologic outcomes were for children who were either normal or abnormal on early examinations.^{3,18,25} We found the greatest correlation for children who were either neurologically suspect or abnormal during the first year. Most infants with transient or persistent neurologic abnormalities during the first year continued to display subtle or overt neurologic deficits at age 5 to 6 years. Thus, transient and persistent neurologic abnormalities during the first year of life seem to be important precursors of persistent neurologic deficits.

The 1-year neurologic score was not an accurate indicator of 5- to 6-year functioning for infants neurologically normal at 1 year of age. At 5 to 6 years there were fewer neurologically normal children. Therefore, a normal 1-year neurologic score did not preclude neurologic dysfunctioning at the age of 5 to 6 years.

Thus, for the 1-year neurologic examination, the sensitivity is better than the specificity; in other words, the chance of detecting abnormal children at 5 to 6 years of age is better than that of identifying healthy survivors. These results should satisfy the goals of the clinician.

The differences between our results and those of previous studies regarding correlations between early and later neurologic outcomes may reflect different study methods. Some previous studies included only infants with "symptomatic" ICH,^{18,25} while others did not account for the presence of ICH at all.³ Furthermore, results of our study may be limited by a small sample size and poor follow-up rate.

In contrast to neurologic outcomes, 5- to 6-year cognitive outcomes did not correlate with either ICH severity or 1-year neurologic outcome. The majority of children had normal IQ scores and abnormal VMI scores despite ICH or 1-year neurologic status. Thus, while most children demonstrated normal

overall cognitive function, they displayed subtle dysfunction in the form of abnormal VMI abilities and other learning disabilities.

The 5- to 6-year neurologic and cognitive sequelae in very-low-birth-weight preterm infants with and without ICH are primarily subtle motor and perceptual dysfunctions. Intracranial hemor-

rhage has significant influence on neurologic outcomes since ICH severity correlated with the extent of neurologic sequelae. Although the school-age abnormalities described are characterized as subtle, they may presage important future problems of learning disability and school failure, making early identification and intervention imperative.

Hypophosphatemia in Breast-fed Low-Birth-Weight Infants Following Initial Hospital Discharge

Robert T. Hall, MD; Robin E. Wheeler, MS, RD; Michael B. Montalto, MS; John D. Benson, PhD

• The present study evaluated 12 infants with birth weights less than 2000 g who received human milk plus a multivitamin supplement and 20 similar infants who received standard cow's milk formula for 16 weeks from the time of initial hospital discharge. Examination at birth, at hospital discharge (study entry), at 4 and 16 weeks after hospitalization, and at 52 weeks of age revealed no intergroup differences in body weight, length, and head circumference. Hypophosphatemia (plasma phosphorus concentration ≤ 1.45 mmol/L) developed in 6 infants fed human milk (5 infants at 4 weeks and 1 infant at 16 weeks of study). Mean vitamin D intakes, but not calcium and phosphorus intakes, were significantly lower during hospitalization in human milk-fed infants with hypophosphatemia (44 [25, SD] IU/d) compared with those without hypophosphatemia (322 [180] IU/d). These data indicate that human milk-fed, low-birth-weight infants are at risk for hypophosphatemia following initial hospital discharge. Plasma calcium, phosphorus, and alkaline phosphatase concentrations at hospital discharge may not predict the infants at risk. Vitamin D supplementation early in the infants' hospital course may prevent hypophosphatemia. (AJDC. 1989;143:1191-1195)

One hypomineralization is a significant problem in low-birth-weight infants exclusively fed human milk.¹⁻⁶ There are adequate data indicating that hypophosphatemia and rickets during the initial hospital course^{1,6} can be prevented in these infants by giving calci-

um, phosphorus, and vitamin D supplements.⁷⁻¹²

However, low-birth-weight infants have been studied infrequently beyond hospitalization.¹³⁻¹⁶ The purpose of the present study was to evaluate biochemical evidence of bone hypomineralization⁸ in human milk-fed low-birth-weight infants compared with formula-fed infants after hospital discharge.

PATIENTS AND METHODS

Infants were eligible for participation in the study if their birth weights were below 2000 g and there were no major congenital malformations, necrotizing enterocolitis, bronchopulmonary dysplasia, malabsorption, or other apparent conditions affecting the nutritional status. Parents were approached regarding their infant's participation, and informed written consent was obtained before entry in the study, which was approved by the Institutional Review Board. No attempt was made to assign infants to the human milk-fed vs formula-fed group. The study was initiated during the week before discharge from the hospital. Management prior to that time was at the discretion of the attending physician. However, calcium, phosphorus, vitamin D, and energy intake measurements were obtained for all infants during initial hospitalization. Mean daily intakes of calcium and phosphorus were derived from human milk composition data of Lemons et al.¹⁶

The human milk-fed group was given 1 mL/d of a multivitamin preparation (Vi-Daylin, Ross Laboratories, Columbus, Ohio) containing 400 IU of vitamin D at hospital discharge. Any previous mineral supplementation was discontinued at study entry. Infants with birth weights below 1500 g generally received supplementation during initial hospitalization with calcium, phosphorus, and vitamin D in the form of powdered human milk fortifier or premature infant formula in accordance with recommendations of the attending physician. Additional supplementation with vitamin D from multivitamin preparations was also given in accordance with recommendations of the attending phy-

sician. No formula supplementation was given to human milk-fed infants during the 16 weeks following hospital discharge.

Formula-fed infants were given a 2800-kJ/L cow's milk formula (Similac With Iron, Ross Laboratories) at study entry during the week prior to hospital discharge. Vitamin supplementation was given to the formula-fed group during hospitalization at the discretion of the attending physician. Infants with a birth weight below 1500 g were generally given a whey-predominant premature infant formula containing 3400 kJ/L that was switched to the 2800-kJ/L formula at study entry. No vitamin supplementation was given following study entry in addition to that present in the formula.

Plasma calcium, phosphorus, and alkaline phosphatase measurements were obtained at study entry and at 4 and 16 weeks following study entry. Body weight, length, and head circumference were obtained by one of us (R.E.W.) at study entry and at 2, 4, 8, 12, and 16 weeks following study entry. From 16 weeks after study entry until 52 weeks of age, infants were not given a prescribed feeding protocol. At 1 year of age, anthropometric measures were made. All weight measurements after study entry were obtained on the same scale calibrated to a 10-g accuracy. Length was obtained with the infant supine on a length board using two attendants. Head circumference measurements were obtained with the same tape measure throughout the study.

Statistical evaluations of differences between groups were made using the Student *t* test for mean values and the Fisher Exact Test for frequencies. A stepwise discriminant analysis was performed using a BMDP 7M program to evaluate differences between infants with and without hypophosphatemia.¹⁷ A plasma phosphorus concentration of 1.45 mmol/L or lower and an alkaline phosphatase concentration of 450 IU/L or greater were considered significantly abnormal.^{3,18,19}

RESULTS

Descriptive data from the infants fed human milk and formula are shown in

Accepted for publication March 7, 1989.

From the Section of Neonatal Medicine, The Children's Mercy Hospital, University of Missouri-Kansas City School of Medicine (Dr Hall and Ms Wheeler); and the Medical Department, Ross Laboratories, Columbus, Ohio (Mr Montalto and Dr Benson). Mr Montalto is now with the Division of Nutritional Sciences, Cornell University, Ithaca, NY.

Reprints not available.

Table 1. The only significant intergroup difference was race; there were significantly more white infants in the human milk group ($P < .001$).

Groups did not differ in growth or absolute weight, length, and head circumference during the first 4 months of the study or at 1 year of age (Table 2).

Mean plasma concentrations of calcium, phosphorus, and alkaline phosphatase were within normal limits and did not differ between the two groups at study entry (Table 3). No infant had a phosphorus concentration of 1.45 mmol/L or lower (hypophosphatemia) or an alkaline phosphatase concentration of 450 IU/L or greater (hyperphosphatasia) at study entry. However, the mean plasma phosphorus concentration was significantly lower and the mean alkaline phosphatase concentration significantly higher in the group fed human

milk by 4 weeks after study entry. These differences persisted at study week 16. No formula-fed infant experienced hypophosphatemia or hyperphosphatasia during the study period.

Stepwise discriminant analysis was performed using 12 variables to distinguish etiologic factors for hypophosphatemia: (1) race, (2) sex, (3) birth weight, (4) length, (5) gestational age, (6) mean vitamin D intake per day, (7) mean calcium intake in kilograms per day, (8) mean phosphorus intake in kilograms per day, (9) mean energy intake in kilograms per day, (10) type of feeding, (11) mean Apgar scores at 1 and 5 minutes of age, and (12) mean weight at 16 weeks. This procedure correctly classified 93.5% of infants using two variables, ie, type of feeding and vitamin D intake. All infants with hypophosphatemia received human milk and had a significant-

ly lower vitamin D intake during hospitalization (mean [SD], 44 [25] IU/d) than infants without hypophosphatemia (322 [180] IU/d, Table 4). This difference was due to low vitamin D intake early in the hospital course of six human milk-fed infants in whom hypophosphatemia developed. Although there was a difference in calcium and phosphorus intake between infants fed formula and human milk, there was not a difference in these mineral intakes in human milk-fed infants with and without hypophosphatemia. Energy intakes were nearly identical among all infants.

Additional evaluation of infants with and without hypophosphatemia appears in Table 5. Mean birth weights of the two groups were 1715 g (infants with hypophosphatemia) and 1611 g (infants without hypophosphatemia; P , not significant). Gestational age and age at study entry were not different. There was likewise no difference in the sex, race, severity of illness, or length of hospital stay between the two groups of human milk-fed infants.

Five of 12 infants had hypophosphatemia at study week 4. A sixth infant had a plasma phosphorus concentration of 1.25 mmol/L at 16 weeks. One infant had hyperphosphatasia at 4 weeks and 2 infants had it at 16 weeks. Three infants required supplementation with calcium and phosphorus because of persistent hypophosphatemia at 16 weeks. One additional infant in the human milk-fed group (patient 13), whose birth weight was 505 g, was dropped from the study at 4 weeks because she had a plasma phosphorus concentration of 1.15 mmol/L and an alkaline phosphatase

*For the formula group compared with the human milk group with hypophosphatemia, P was not significant for energy intake, $P = .006$ for calcium intake, $P = .0004$ for phosphorus intake, and $P = .0001$ for vitamin D intake; for the formula group compared with the human milk group without hypophosphatemia, P was not significant for energy intake and vitamin D intake, $P = .058$ for calcium intake, and $P = .005$ for phosphorus intake; and for the human milk group with hypophosphatemia compared with the human milk group without hypophosphatemia, P was not significant for energy intake, calcium intake, and phosphorus intake and $P = .0008$ for vitamin D intake.

concentration of 910 IU/L; she was given supplementation with calcium and phosphorus.

Linear growth by SD from normal median values²⁰ in the infants with and without hypophosphatemia is presented in Table 6. There were no significant differences, although the infants with hypophosphatemia always had a slightly greater length percentile and incremental growth compared with infants without hypophosphatemia.

COMMENT

Data from the present study indicate that hypophosphatemia and hyperphosphatemia, which are plasma markers for bone hypomineralization and rickets, occur in a large percentage of low-birth-weight infants following hospitalization in spite of normal values at discharge. In

the present study, these infants were confined to those who were fed human milk but failed to receive adequate vitamin D supplementation. This finding was unexpected, since infants were receiving supplemental calcium, phosphorus, and vitamin D with human milk fortifier or premature formula during hospitalization. However, the powdered fortifier provided only 260 IU of vitamin D per 100 mL of fortified breast milk (1 package contains 25 mL), and the liquid fortifier provided only 61 IU of vitamin D per 100 mL when added to an equal volume of breast milk. Calculation of vitamin D intakes from hospital records revealed that all six infants with hypophosphatemia had prolonged periods of minimal vitamin D intake early in their hospital course. This was due to the perception that the multivitamin

preparations commonly used either were causing gastric residuals and abdominal distention or were associated with an increased risk of necrotizing enterocolitis from hyperosmolality.²¹

It is of interest that hypophosphatemia developed in human milk-fed infants with a low vitamin D intake who received calcium and phosphorus supplements in quantities similar to infants with higher vitamin D supplementation in whom hypophosphatemia did not develop. Four of six infants who experienced hypophosphatemia had a birth weight between 1500 and 2000 g. Previous reports have generally emphasized very-low-birth-weight infants (<1500 g) as the population at risk.

Linear growth in human milk-fed infants, including those who experienced hypophosphatemia, was not different from that in formula-fed infants during the 16-week study period and was within normal limits at 1 year of age. Greer et al²² reported decreased body length at 1 year of age in solely breast-fed term infants without vitamin D supplementation. However, three infants in our group with hypophosphatemia that persisted to 16 weeks did receive calcium and phosphorus supplements until their hypophosphatemia resolved.

The present data indicate that biochemical markers of bone mineralization obtained at the time of hospital discharge may not predict the preterm infant at risk for hypophosphatemia. The data emphasize the importance of vitamin D supplementation, particularly in low-birth-weight infants fed human milk. Concentrations of vitamin D present in human milk fortifiers do not meet the needs of low-birth-weight infants. A large dose of intramuscular vitamin D given early in the hospital course might have prevented hypophosphatemia in the infants who did not receive adequate supplementation.

Additional factors in the development of hypophosphatemia may be variability in the concentrations of calcium and

Nasal Intermittent Positive-Pressure Ventilation Offers No Advantages Over Nasal Continuous Positive Airway Pressure in Apnea of Prematurity

C. Anthony Ryan, MB, MRCP(Ire), MRCP(UK), FRCP(C);

Neil N. Finer, MD, FRCP(C); Katherine L. Peters, RN, BScN, MN

• A prospective, randomized, crossover trial was performed to compare the efficacy of nasal intermittent positive-pressure ventilation with nasal continuous positive airway pressure in infants of less than 32 weeks of gestation. Continuous positive airway pressure was delivered at end-expiratory pressures of 4 cm H₂O, while peak pressures of 20 cm H₂O and end-expiratory pressures of 4 cm H₂O were used during nasal intermittent positive-pressure ventilation at ventilatory rates of 20 breaths per minute. The frequency and extent of apnea and bradycardia during a 6-hour period in a patient receiving nasal continuous positive airway pressure were compared with a similar crossover period of nasal intermittent positive-pressure ventilation. Although the infants had slightly less frequent episodes of apnea per hour (0.6 ± 0.7 vs 0.5 ± 0.7) and bradycardia per hour (1.2 ± 1.3 vs 0.9 ± 1.0) during nasal intermittent positive-pressure ventilation, these differences were not significant. There were no significant differences in the severity of these events as assessed by the duration and fall in transcutaneous oxygen pressure during apnea and heart rate during bradycardia. There were no significant changes in blood gases throughout the study. Nasal intermittent positive-pressure ventilation appears to have no advantages over nasal continuous positive airway pressure in preventing apnea and does not alter gas exchange in infants of less than 32 weeks of gestation.

(AJDC. 1989;143:1196-1198)

Continuous positive airway pressure (CPAP) by the nasal route is a useful adjunct to neonatal ventilatory management. It is widely used in the management of neonatal respiratory distress syndrome¹⁻³ and apnea of prematurity^{4,5}

as a method of weaning infants from ventilators.⁶

In addition to using CPAP by the nasal route, we have used intermittent positive-pressure ventilation (IPPV) by nasal prongs and nasopharyngeal tubes in infants of 32 weeks of gestation or less in an attempt to avoid intubation for apnea or respiratory failure. Despite scant evidence in the literature for this practice, a questionnaire sent to the directors of 19 tertiary care nurseries in Canada showed that 9 (53%) of 17 had also used nasal IPPV as a form of ventilatory support for these infants. While 3 of the latter respondents no longer used nasal IPPV, the remainder said they found it of benefit in clinical practice, particularly in managing infants with low birth weights (C.A.R., unpublished data, April 1986).

A prospective, randomized, crossover trial was therefore initiated to clarify the role of nasal IPPV by comparing its efficacy with that of nasal CPAP on gas exchange and apnea in infants of less than 32 weeks of gestation.

PATIENTS AND METHODS

Infants of 32 weeks of gestation or less by maternal dates or early obstetric ultrasound and who were treated by nasal CPAP for apnea of prematurity by the attending neonatologists were eligible for the study. Known causes of apnea were excluded. The infants were, without exception, receiving aminophylline and were in stable condition, except for their apneic episodes, at the time of study.

Both CPAP and nasal IPPV were delivered by a Baby Bird ventilator (Bird Corp, Palm Springs, Calif) at end-expiratory pressures of 4 cm H₂O during CPAP and peak pressures of 20 cm H₂O and end-expiratory pressures of 4 cm H₂O during nasal IPPV. These pressures were measured at the proximal end of the nasal prongs or nasopharyngeal tube by a pressure transducer (model MP45-4, Validyne Engineering Corp, Northridge, Calif) when the outlet was occluded. The ventilatory rate was set at 20 breaths per minute during nasal IPPV.

After obtaining informed parental consent, a baseline blood gas measurement while the infant was receiving CPAP was taken, and the infants were randomized to either CPAP or nasal IPPV according to a computer-generated randomization schedule. After receiving CPAP or nasal IPPV for 2 hours, a blood gas measurement was repeated. After receiving one mode for 6 hours (CPAP or nasal IPPV), a third blood gas measurement was taken and the infant was switched to the alternative mode. Two further blood gas determinations were taken after 2 and 6 hours on the alternative mode. In infants with indwelling arterial catheters, arterial blood gases were determined. "Arterialized" capillary gases were measured in the remaining infants, since, in well-perfused infants, arterialized capillary PCO₂ has an excellent correlation with arterial PCO₂.⁷ All infants were monitored with a transcutaneous PO₂ (tcPO₂) electrode (model 632, Roche Medical Electronics Inc, Everett, Mass) and the tcPO₂ at the time of the blood gas measurements, rather than the capillary PO₂ reading, was analyzed when a capillary gas measurement was taken.

The heart rate, respiratory impedance, tcPO₂, and proximal airway pressures were simultaneously recorded throughout the study on a four-channel recorder (model 7404A, Hewlett Packard Industrial Recorder, Medical Electronics Division, Waltham, Mass). At the end of the study period the tracings were analyzed, and the apnea attack rates with the infant receiving CPAP and nasal IPPV were documented. Significant apnea was defined as the cessation of spontaneous respirations for more than 15 seconds with an associated decrease in tcPO₂ of more than 5 mm Hg and/or a decrease in heart rate of more than 20% of the baseline heart rate. Significant bradycardia was defined as a decrease in heart rate of more than 20% of the baseline heart rate. Apnea and/or bradycardia that occurred during nursing interventions were not included in the study.

Based on previously published variability of apnea in infants of less than 32 weeks of gestation in this unit,⁸ 20 subjects were required, according to the tables of Machin and Campbell,⁹ to detect a 50% reduction in apnea with nasal IPPV compared with nasal CPAP at a power of 80% ($\alpha = .05$, one-tailed

Accepted for publication March 27, 1989.

test). Statistical analysis of the means was performed with a paired Student *t* test (two-tailed test) and analysis of variance when more than 2 means were tested. $P < .05$ was considered significant and data are reported as mean \pm SD. The protocol was approved by the Clinical Investigation Committee of the Royal Alexandra Hospitals, Edmonton, Canada.

RESULTS

Demographic data on the 20 infants are presented in the following tabulation:

Value	Mean \pm SD (Range)
Birth Weight, g	923 \pm 292 (540-1600)
Gestation, wk	26 \pm 2 (22-32)
Weight at study, g	979 \pm 315 (530-1655)
Age at study, d	25.0 \pm 15.6 (3-56)

The mean fraction of inspired oxygen during the study was 0.29 ± 0.1 (range, 0.21 to 0.6). End-expiratory pressures measured at the proximal airway during nasal CPAP and IPPV varied from 2 to 4 cm H₂O, while the peak pressures during nasal IPPV varied from 8 to 21 cm H₂O, averaging approximately 10 cm H₂O.

The frequency and extent of apnea and bradycardia when comparing the 6-hour period that the infants were receiving nasal CPAP with a similar crossover period receiving nasal IPPV are presented in the Table. Although infants receiving nasal IPPV had slightly less frequent episodes of apnea and bradycardia per hour, these differences were not significant. In addition, there were no significant differences in the severity of these events as assessed by the duration and the fall in $tcPo_2$ during apnea and heart rate during bradycardia.

The $Paco_2$, Pao_2 , and alveolar-to-arterial oxygen gradient did not change significantly throughout the study. There were no significant differences in these values when comparing the period that the infants were receiving nasal CPAP with that when infants were receiving nasal IPPV (Table).

COMMENT

Our study was not designed to examine the efficacy of nasal CPAP in the management of apnea of prematurity,

Comparison Between Nasal CPAP and Nasal IPPV*		
	Nasal CPAP	Nasal IPPV
Apnea, No. of episodes per hour	0.6 \pm 0.7	0.5 \pm 0.7
Longest apnea episode, seconds	23 \pm 20	21 \pm 22
Greatest decrease in $tcPo_2$, mm Hg	17 \pm 15	14 \pm 11
Bradycardia, No. of episodes per hour	1.2 \pm 1.3	0.9 \pm 1.0
Greatest decrease in heart rate, beats per min	66 \pm 36	56 \pm 43
$Paco_2$ at 0 h, mm Hg	44 \pm 6	45 \pm 8
$Paco_2$ at 2 h, mm Hg	44 \pm 8	45 \pm 7
$Paco_2$ at 6 h, mm Hg	43 \pm 7	44 \pm 8
Pao_2 at 0 h, mm Hg	58 \pm 10	57 \pm 13
Pao_2 at 2 h, mm Hg	57 \pm 12	56 \pm 13
Pao_2 at 6 h, mm Hg	55 \pm 12	61 \pm 15

*Values are given as mean \pm SD. CPAP indicates continuous positive airway pressure; IPPV, intermittent positive-pressure ventilation. $tcPo_2$ indicates transcutaneous Po_2 .

because this form of therapy has already been shown to be advantageous.^{4,5} Rather, we were interested in seeing whether nasal IPPV was more effective than nasal CPAP in preventing apnea episodes in infants of less than 32 weeks of gestation. We have shown, in the present prospective randomized crossover trial, that nasal IPPV did not reduce the incidence of apnea, when compared with nasal CPAP, in this population. The choice of a 6-hour trial before and after crossover was arbitrary. This period needed to be long enough to document a minimum number of apnea episodes and yet not so prolonged as to introduce other variables, such as a natural improvement in the infants' condition over time.

Based on a sample size of 20 infants, we can be confident that a 50% or higher increase in the incidence of apnea during nasal IPPV was not missed by our study. Because infants ventilated with nasal prongs or face masks are 30 times more likely to suffer gastric perforations than infants ventilated with endotracheal tubes,¹⁰ we believed that such a reduction in the incidence of apnea would have been warranted to justify the continued use of nasal IPPV.

Although nasal CPAP has proved effective in the treatment of obstructive and mixed apnea,^{4,5} the mechanism of action has not been fully elucidated. It may involve improved oxygenation, altered respiratory reflexes, or both.¹¹⁻¹³ Hagan et al¹¹ have postulated that CPAP may stabilize the rib cage and so reduce inhibitory neural input to the respiratory control center. It may also act in reducing apnea incidence by improving oxygenation secondary to lung

inflation¹² or by eliminating the Hering-Breuer deflation reflex.¹³ It has also been suggested that its action is related to improved patency of the upper airway either by activation of dilator muscles or by passive splinting, thus reducing the incidence of obstructive apnea.^{5,14} We had postulated that nasal IPPV might enhance the latter effect by producing higher mean pharyngeal pressures and, in addition, might abort some apneic spells by the intermittent inflation of the hypopharynx, through a mechanism known as Head's paradoxical reflex.

It could be argued that nasal IPPV may have a more beneficial effect on obstructive apnea as opposed to centrally mediated apnea. Over 40% of apneic spells in premature infants are mixed or obstructive.⁸ Miller et al⁸ showed that CPAP reduces only obstructive and mixed apneic spells, with no effect on central apnea. We did not monitor nasal airflow in our study and thus were unable to differentiate between the various forms of apnea (central, obstructive, or mixed). It is impossible to distinguish between ventilator-generated air flow and spontaneous breaths with instruments used to determine the absence of airflow during obstructive apnea (eg, nasal thermistors or end-tidal carbon dioxide), especially during nasal IPPV.

Perhaps of less surprise in this study was the lack of support for nasal IPPV as a method of ventilation when compared with nasal CPAP in that no significant decrease in $Paco_2$ was observed during nasal IPPV. We found that peak airway pressure at the proximal airway during nasal IPPV was approximately

Illustration of bradycardia-associated apnea in an infant receiving nasal intermittent positive-pressure ventilation. Despite proximal airway pressures of 21 per 4 cm H₂O, no chest wall movement was detected on the respiratory impedance tracing, consistent with upper airway obstruction. tc indicates transcutaneous.

half the peak pressure when the outlet was occluded. Pharyngeal pressures during nasal CPAP are dependent on the presence of a seal between the tongue and soft palate.¹⁶ Nasal IPPV may thus have failed as a mode of ventilation in the current study, either because of poor transmission or attenuation of the applied pressure into the lungs. It may be possible to ventilate infants with pressures higher than those used in our study. However, we would not support this practice because the potential hazards of gastric distention and perforation far outweigh the risks of endotracheal intubation and ventilation.¹⁰

It is of interest to note that the peak pressures during IPPV were not transmitted to the chest wall during an apneic episode in one infant (Figure). No changes in respiratory impedance were observed in this tracing despite measured pressures of 21 per 4 cm H₂O at the proximal airway. This is consistent with the development of upper airway obstruction during an apneic episode. Gauda et al¹⁶ showed, by genioglossus electromyography, that premature infants with mixed and obstructive apnea are less apt to recruit their upper airway dilating muscles in response to spontaneous obstruction. We have observed that nasal IPPV, even at rela-

tively high pressures, did not relieve this obstruction.

We conclude that nasal IPPV at the rates and pressures employed in our study appears to have no advantages over nasal CPAP in preventing apnea of prematurity and does not reduce PaCO₂ in infants of less than 32 weeks of gestation. It may be associated with greater risks and is therefore not recommended as a mode of respiratory support in these infants.

We wish to thank Jo-Ann Kimball, RN, and Liz Katz, RRT, for analyzing the respiratory tracings and K. Barrington, MB, for his help with the statistical analysis.

Pertussis in Neonates

Celia D. C. Christie MB,BS, DM Peds, Robert S. Baltimore, MD

• Despite the increasing prevalence of pertussis in young adults and infants, reports of maternal-neonatal pertussis are rare. Our study involves three neonates who apparently acquired pertussis from their adolescent mothers. The diagnosis of pertussis was initially missed in all of the patients. The mothers had mild respiratory disease. All three newborns presented with life-threatening coughing and choking spells without a characteristic inspiratory whoop. Two neonates had apnea, bradycardia, cyanosis, and unresponsiveness, but were without the initial lymphocytosis that is distinctive of pertussis. These two neonates had a clinical course that was consistent with the historic "100-day-cough." They required prolonged ventilatory support and hospitalization at a high cost. The other neonate had a terminal pulmonary hemorrhage. Strategies for the early diagnosis, treatment, and prevention of this potentially lethal disease in neonates are discussed. (AJDC. 1989;143:1199-1202)

The prevalence of pertussis in infancy and early childhood has increased in recent years. Over 50% of all reported cases now occur in infants.^{1,2} Susceptible children have an attack rate of 81% from exposure to household contacts.³ Natural immunity to pertussis is lifelong, whereas 12 years after vaccination, 95% of the vaccinees are susceptible to pertussis.⁴ Adults and adolescents, especially females, with waning immunity and mild disease become the major reservoir for transmission of pertussis to unimmunized infants.² Seventy percent of the pertussis mortality occurs in infancy, with severe transient morbidity in many nonfatal cases.^{5,6} Although per-

tussis agglutinins are present in one third of maternal and neonatal serum samples, passive transplacental immunity does not reliably protect against neonatal infection.⁷

In this article, we describe three unusual maternal-neonatal patient-pairs with pertussis who presented to the Yale-New Haven (Conn) Hospital during a 1-year period. We also review the literature and highlight the strategies for the diagnosis, treatment, and prevention of this potentially lethal disease in neonates.

PATIENT REPORTS

PATIENT 1.— A full-term female infant was admitted to a community hospital in Connecticut at 26 days of age for increasing respiratory distress. The infant was examined four times at a local clinic for frequent coughing, choking, and poor feeding, which began at 20 days of life. Her 17-year-old mother was treated simultaneously with amoxicillin for a sore throat and a prolonged repetitive cough.

On hospital admission, the infant was afebrile, with a respiratory rate of 60 breaths per minute and a pulse rate of 200 beats per minute. There were moderate chest retractions and diffuse pulmonary crepitations. A chest roentgenogram revealed patchy peribronchial infiltrates radiating from the hila, with diffuse hyperinflation in both lung fields. The hemoglobin level was 111 g/L; hematocrit, 0.33; and white blood cell count, $63 \times 10^9/L$, with 0.26 segmented neutrophils, 0.26 band forms, 0.38 lymphocytes, 0.01 monocytes, 0.02 eosinophils, 0.03 myelocytes, and 0.04 metamyelocytes. Bacterial cultures of blood, cerebrospinal fluid, and urine were performed, and parenteral ampicillin sodium and gentamicin sulfate therapy commenced. Respiratory deterioration in the ensuing 24 hours led to admission to the Yale-New Haven Pediatric Intensive Care Unit.

On hospital arrival, the infant was intubated, afebrile, and in marked respiratory distress. Blood gases in 100% inspired oxygen showed a pH of 7.19, a PCO_2 of 67%, and a PO_2 of 98%. The white blood cell count was $92 \times 10^9/L$ (0.42 segmented forms, 0.22 band

forms, 0.10 lymphocytes, 0.06 atypical lymphocytes, 0.04 monocytes, 0.02 eosinophils, 0.05 myelocytes, 0.02 metamyelocytes, 0.02 promyelocytes, and 0.05 blasts). Platelet counts, partial thromboplastin time, and prothrombin time were elevated. Despite assisted ventilation, bradycardia, hypotension, and acidosis developed, and pulmonary compliance decreased. The hematocrit value fell from 0.30 to 0.16 within 4 hours. A chest roentgenogram showed increased bilateral consolidation and an enlarged cardiac silhouette. An electrocardiogram revealed the ST-wave changes of subendocardial ischemia. An echocardiogram showed an open foramen ovale, dilated right ventricle and right atrium, and poor contraction of the left ventricle. The infant died 12 hours after admission.

Postmortem examination revealed a fenestrated patent foramen ovale and an increased combined weight of both lungs (124 g). The cut surfaces showed atelectasis and extensive hemorrhage throughout the apex of the left lung. Histologic sections revealed bilateral pulmonary edema and focal hemorrhages, with diffuse infiltration by macrophages and moderate focal infiltration with inflammatory cells. The right lower lobe and entire left lung showed extensive necrotizing bronchopneumonia and thromboemboli.

Bordetella pertussis was isolated after 17 days from postmortem cultures of respiratory secretions and lung sections on Regan-Lowe medium and confirmed by fluorescent antibody staining. There were no other significant bacterial pathogens isolated.

PATIENT 2.— A male infant was one of dizygotic twins delivered at 36 weeks of gestation because of maternal preeclampsia. He was admitted to an outlying hospital at 21 days of age with a 1-day history of cough, coryza, vomiting, cyanosis, inactivity, and limpness followed by temporary cessation of respiratory efforts that responded to stimulation.

Examination revealed an afebrile infant with tachypnea and fine pulmonary rales. Occasional cough, cyanotic spells with apnea, and bradycardia were documented. Oxygen therapy as well as parenteral ampicillin and gentamicin therapy were commenced. Deterioration in respiratory status over 7 hours necessitated tracheal intubation and transfer to the Yale-New Haven Hospital Pediatric

Intensive Care Unit. Blood gases in 100% inspired oxygen showed a pH of 7.25, a PO_2 of 73%, and a PCO_2 of 21.6%. The hemoglobin level was 148 g/L, the white blood cell count was $98 \times 10^9/L$ (0.41 segmented neutrophils, 0.09 band forms, 0.39 lymphocytes, 0.09 monocytes, and 0.03 atypical lymphocytes), and the platelet count was $513 \times 10^9/L$. He was hypoglycemic. Bacterial cultures of blood, cerebrospinal fluid, and urine were performed. Central apnea was diagnosed in view of the predominant findings of apnea and bradycardia, with a family history of sudden infant death syndrome in a 6-month old sibling.

The infant was intubated and underwent ventilation for 6 days. On extubation, apnea and bradycardia were again evident. Copious, thick nasopharyngeal secretions and collapse-consolidation in the right lung fields led to reintubation and ventilation 3 days later. The infant had a temperature of $39^\circ C$ on the 11th hospital day, with roentgenographic evidence of progressive right pulmonary consolidation and compensatory emphysema in the left lung. The white blood cell count was now $41 \times 10^9/L$ (0.27 segmented neutrophils, 0.32 band forms, 0.20 lymphocytes, 0.14 monocytes, 0.01 basophils, 0.04 atypical lymphocytes, and 0.02 metamyelocytes). The platelet count was $840 \times 10^9/L$.

The Pediatric Infectious Diseases Service of the Yale-New Haven (Conn) Hospital was consulted. The infant's 17-year-old mother had peripartum coryza-like symptoms, with severe repetitive protracted cough, which was suggestive of pertussis. *Bordetella pertussis* was later isolated from the infant's nasopharyngeal secretions and confirmed by a direct fluorescent antibody test. Erythromycin ethyl succinate was administered to the neonate and his close contacts. Oxacillin sodium and gentamicin were prescribed for the probability of secondary bacterial invaders. Respiratory isolation was begun. The infant was ventilator-dependent for 6 weeks. He received aerosolized ribavirin; his nasopharyngeal secretions were negative for respiratory syncytial virus by immunofluorescence, but he was treated because his twin sister (patient 3, discussed below) was infected with the virus. Chest roentgenograms after assisted ventilation revealed interstitial scarring. Apneic spells and cough resolved after 3 months. Weight gain continued below the fifth percentile for age because of vomiting and poor feeding. He had developmental delay. He was hospitalized for 4 months.

PATIENT 3.—The female sibling of patient 2 was admitted to the hospital 1 day after her twin brother. She was 22 days old, with a 1-day history of difficulty breathing, cyanosis, and one episode of respiratory cessation that responded to mouth-to-mouth resuscitation. On admission to the Yale-New Haven Pedi-

atric Intensive Care Unit, coughing spells, apnea, bradycardia, cyanosis, limpness, pallor, irregular and shallow respiratory efforts, and rales in the left lung were present. She required ventilatory support for 10 days. A chest roentgenogram revealed collapse-consolidation in the right upper lobe, with compensatory emphysema. The white blood cell counts on admission and on the eighth day, respectively, were 69 and $151 \times 10^9/L$ (0.48 segmented neutrophils, 0.03 band forms, 0.40 lymphocytes, 0.08 monocytes, and 0.01 eosinophils).

Evaluation by the Yale-New Haven Hospital Infectious Diseases Service on the 11th hospital day revealed a paroxysmal staccato cough characterized by 6 to 10 explosive bursts within one expiratory effort followed by apnea, bradycardia, and cyanosis. Coughing spells were initiated by any manipulation (eg, suctioning) and were followed by prostration, lethargy, and limpness. They were also associated with thick, tenacious respiratory secretions and were unaccompanied by an inspiratory whoop. Chest roentgenograms demonstrated progressive collapse-consolidation in the right lung fields with a corresponding mediastinal shift to the right and hyperaeration in the left lung fields. Nasopharyngeal secretions subsequently yielded *B pertussis*. Erythromycin therapy was discontinued because of gastrointestinal upset. Trimethoprim-sulfamethoxazole therapy was commenced instead. Mucus plug obstruction of a large airway led to a respiratory arrest. She was successfully resuscitated and required additional ventilatory support for 6 weeks. Respiratory syncytial virus was identified by immunofluorescent staining. Chest roentgenograms showed residual interstitial scarring. Apnea remitted at $2\frac{1}{2}$ months. She was discharged with persistent cough, developmental delay, and a weight below the fifth percentile after 3 months in the hospital.

COMMENT

These teenage mothers were the apparent point-source of pertussis in all 3 of the neonates described herein. Although the prevalence of pertussis in infancy has increased considerably in recent years, the scope of the problem of maternal-neonatal pertussis seems underestimated.

Neonatal pertussis was first reported in 1913 by Cockayne⁸ who described a 5-day-old neonate who contracted pertussis from family members; he also alluded in this article to Sir Thomas Watson, who reported that "the newcomer 'hooped on the first day he appeared in the world,'" and to Rilliet and Barthez,

who described another neonate who whooped on the first day of life. In 1921, Phillips⁹ described an obstetric nurse who infected 2 newborns under her care. Lapin,¹⁰ in 1943, described newborns with congenital pertussis in his book. Early reports of pertussis with onset at 4 to 7 days of life were also documented outside the English literature.¹¹⁻¹³ In none of these earlier neonates, however, was the diagnosis of pertussis proven. *Bordetella pertussis* was first isolated from a neonate in 1951.¹⁴ Linneman et al,¹⁵ in 1975, documented a hospital epidemic in which a 1-month-old infected a house officer, who subsequently passed on the disease to 6 newborns. Eleven of 400 patients with pertussis described by Nelson² in 1978 occurred in neonates; in 6 newborns, an adult was the source; in 2 newborns, the source was another child; and in 3 newborns, the source was unknown. McGregor and colleagues¹⁶ in 1984 described proven pertussis in three mother-infant pairs.

The pathophysiologic features of pertussis have been elucidated by the recognition of a protein exotoxin comprised of lymphocytosis-promoting factor, histamine-activating factor, and islet cell-activating factor.¹⁷ Some of the effects include entrapment of the lymphocytes within the vascular compartment, hypoglycemia, and abnormal function of the heart cells. The toxin also causes paralysis of the cilia of the respiratory epithelial cells, leading to increased mucus production and the characteristic cough. The fact that the disease continues unabated, despite antibiotic eradication of *B pertussis*, unless antibiotics are administered early in the catarrhal stage, strongly implicates the pertussis toxin in the pathogenesis of the disease.

After an incubation period of 5 to 14 days, the catarrhal phase of the illness begins. This is usually characterized by 1 to 2 weeks of upper respiratory tract symptoms and low-grade fever. This phase coincides with bacterial multiplication within the respiratory epithelium. This phase was characteristically contracted or absent in all three neonates discussed in the present article. The protein exotoxin, secreted by the bacteria, mediates the paroxysmal phase, which may last 6 to 14 weeks. This phase is usually characterized by

paroxysmal staccato coughing with an inspiratory whoop, which was absent in all three newborns. Instead, life-threatening coughing and choking spells followed by apnea, cyanosis, bradycardia, and unresponsiveness were the main symptoms. Increased mucus production that produced bronchial obstruction with alternating areas of pulmonary collapse-consolidation and emphysema as well as the roentgenographic features of perihilar shaggy infiltrates obscuring the heart border are also characteristic of this phase. A 2- to 3-week convalescent phase then follows.¹⁸ All three phases can be contracted in the neonate; although in the two neonates who survived, the course was consistent with the historic "100-day-cough."

The diagnosis of pertussis was significantly delayed in all three neonates, resulting in the late commencement of the specific control measures of respiratory isolation and erythromycin therapy for young adult pertussis-susceptible caretakers and to ill infants in the intensive care unit. First, the history and significance of maternal peripartum protracted cough was missed. Adults have waning vaccine-induced immunity and commonly present only with prolonged repetitive cough, instead of the full-blown pertussis syndrome with an inspiratory whoop and posttussive vomiting.^{19,20} At the time the infant presents with the illness, the adult's infection may have also progressed to the point where *B pertussis* can no longer be recovered by culture. Second, the absence of an inspiratory whoop was not recognized as a characteristic of neonatal pertussis. Third, although apnea, cyanosis, bradycardia, and unresponsiveness are typical of neonatal pertussis, the significance of paroxysmal cough and increased respiratory secretions were masked by ventilatory support and the presence of sudden infant death syndrome in a sibling. Fourth, the characteristic lymphocytosis that would have led to the suspicion of pertussis or would have supported the diagnosis of pertussis was absent in the early paroxysmal phase in the twins. This is a recognized feature of neonatal pertussis.^{21,22} Fifth, the laboratory diagnosis was further delayed in all of the infants by the presence of competing gram-negative flora that inhibited the growth of *B pertussis*. For

this reason, nasopharyngeal swabs or nasal washings are preferable to sputum or tracheal aspirates for the efficient isolation of this fastidious organism. Similar delays in the diagnosis of pertussis have led to nosocomial pertussis infection in two large hospital epidemics that involved medical personnel and other susceptible infants receiving intensive care.^{16,23}

Complications occur more frequently and with increased severity in the neonate. These include the interstitial bronchopneumonia of adenovirus, respiratory syncytial virus, or cytomegalovirus; any of these agents may coexist with *B pertussis*, as shown by the twins in our study, or may be the primary etiologic agent of the pertussis syndrome.^{16,24,25} Lobar pneumonia secondary to *Pneumococcus*, *Staphylococcus*, or hospital-acquired gram-negative organisms may be heralded by fever and leukemoid reaction with blasts in the peripheral blood, as well as by the clinical and roentgenographic evidence of progressive pneumonic consolidation; lobar pneumonia is the usual cause of death.²¹ Bronchiectasis, pneumothorax, and pneumomediastinum also occur. Respiratory arrest from airway obstruction by a mucus plug was evident in the second newborn. This complication is another cause of sudden death. Other complications include convulsions from asphyxia, subarachnoid hemorrhage, encephalopathy, cortical atrophy, and hypoglycemia. Severe and prolonged hypoglycemia was present initially in the second newborn and might have been the direct effect of the pertussis toxin. Developmental delay was present in the twins in our study. This may result from the multiple central nervous system complications or from prolonged hospitalization and ventilatory support without adequate stimulation. Repeated vomiting leads to hypocalcemic tetany, metabolic acidosis, dehydration, and malnutrition, as was present in the twins; hernias and prolapse of the rectum may also occur. Increased venous pressure from the vomiting and coughing results in petechiae and subconjunctival and intracranial hemorrhages.⁸ To our knowledge, a bleeding diathesis with terminal pulmonary hemorrhage in a neonate with pertussis (patient 1) has not been previous-

ly reported.

Prevention of perinatal pertussis is aided by efficient patient diagnosis and infant immunization. A 14-day course of erythromycin administered early in the catarrhal phase shortens the period of communicability^{26,27} and may modify the course of the illness. Close contacts may be protected by erythromycin therapy and active immunization—especially for those with chronic lung disease. Trimethoprim-sulfamethoxazole is the substitute therapy for patients with erythromycin intolerance.²⁷ Close contacts who have not completed the primary diphtheria and tetanus toxoids and pertussis vaccine series plus a booster appropriate for age and those who have not received this vaccine within 3 years of exposure should be given a dose of the vaccine.²⁷ During a pertussis epidemic, the vaccine may be given to infants at 1 month of age.⁷ The pertussis vaccine is not recommended for routine adult immunization. Respiratory isolation should be instituted for 5 days during antibiotic therapy. Treatment or prophylaxis with pertussis immunoglobulin was abandoned when controlled trials showed no benefit.²⁸

Three newborns who apparently acquired pertussis from their teenage mothers are described. Young adults with waning immunity and mild atypical disease are the source of infection to susceptible infants. Neonatal pertussis is rarely associated with the characteristic whoop or lymphocytosis. Instead, newborns present with life-threatening coughing spells associated with apnea, bradycardia, cyanosis, and unresponsiveness. Complications require prolonged, costly hospitalization and ventilatory support. Early patient identification, antimicrobial chemotherapy to the index patient and to exposed medical and household contacts, as well as immunization for susceptible infants during epidemics are necessary to prevent this potentially lethal disease.

Since the initial submission of this report in February 1989, we have treated a 5-month-old unimmunized infant whose parents had a 1-month history of "bronchitis" that was unresponsive to antibiotic therapy. This infant presented with apneic spells, fever, and cough without paroxysms or whoop. She de-

veloped a leukemoid reaction of $85 \times 10^9/L$ white blood cells, with blasts in the peripheral blood and died of an overwhelming pneumonia. *Bordetella pertussis* was isolated from the respiratory secretions before death and from a specimen of hemorrhagic lung at autopsy.

The W. K. Kellogg Foundation, Battlecreek, Mich, funded a 2-year fellowship in Pediatric Infectious Diseases and Epidemiology for Dr Christie at Yale University School of Medicine. James W. Bass, MD, MPH, and John D. Nelson, MD, provided editorial assistance.

Growing up on a steady theophylline is an open-and-shut case

Sprinkled

Intact

Changing your patients from sprinkled to solid theophylline administration shouldn't mean changing their serum levels as well. With Slo-bid, you won't change a thing when your younger asthma patients are ready to switch to intact administration.

Slo-bid maintains steady theophylline levels when switching from sprinkled to solid administration¹

Mean Serum Theophylline Concentration in 14 Children Dosed With Slo-bid Sprinkled and Slo-bid Intact

Switching from Slo-bid sprinkled to Slo-bid intact causes virtually no change in serum levels. Since the release system doesn't change, theophylline performance with both forms is identical. There's no need to restabilize your patients when they switch to taking capsules. In addition, capsules are the dosage form more patients prefer to take.²

Keep your patients' theophylline levels steady. Start and stay with Slo-bid. It's the perfect theophylline system for asthma patients to grow up with.

Slo-bid

(theophylline, anhydrous)

50 mg, 75 mg, 100 mg, 125 mg, 200 mg, and 300 mg

Gyrocaps®

Timed-Release Capsules

BRIEF SUMMARY

DESCRIPTION: Slo-bid™ Gyrocaps® contain 50 mg, 75 mg, 100 mg, 125 mg, 200 mg, or 300 mg theophylline anhydrous in the form of long-acting beads within a dye-free hard gelatin capsule and are intended for oral administration. Slo-bid Gyrocaps can be administered with a 12-hour dosing interval for a majority of patients and a 24-hour dosing interval for selected patients (see DOSAGE AND ADMINISTRATION section in full prescribing information for description of appropriate patient population).

INDICATIONS AND USAGE: For relief and/or prevention of symptoms from asthma and reversible bronchospasm associated with chronic bronchitis and emphysema.

CONTRAINDICATIONS: Slo-bid is contraindicated in individuals who have shown hypersensitivity to any of the components of this product. It is also contraindicated in patients with active peptic ulcer disease and in individuals with underlying seizure disorders (unless receiving appropriate anticonvulsant medication).

WARNINGS: Serum levels above 20 µg/mL are rarely found after appropriate administration of the recommended doses. However, in individuals in whom theophylline plasma clearance is reduced for any reason, even conventional doses may result in increased serum levels and potential toxicity. Reduced theophylline clearance has been documented in the following readily identifiable groups: 1) patients with impaired renal or liver function; 2) patients over 65 years of age, particularly males and those with chronic lung disease; 3) those with cardiac failure from any cause; 4) patients with sustained high fever; 5) neonates and infants under 1 year of age; and 6) those patients taking certain drugs (see PRECAUTIONS, Drug Interactions). Frequently, such patients have markedly prolonged theophylline serum levels following discontinuation of the drug.

Reduction of dosage and laboratory monitoring is especially appropriate in the above individuals.

Serious side effects such as ventricular arrhythmias, convulsions, or even death may appear as the first sign of toxicity without any previous warning. Less serious signs of theophylline toxicity (i.e., nausea and restlessness) may occur frequently when initiating therapy but are usually transient, when such signs are persistent during maintenance therapy they are often associated with serum concentrations above 20 µg/mL. Stated differently, *serious toxicity is not reliably preceded by less severe side effects*. A serum concentration measurement is the only reliable method of identifying a potential for life-threatening toxicity.

Many patients who require theophylline exhibit tachycardia due to their underlying disease process, so the cause/effect relationship to elevated serum theophylline concentrations may not be appreciated.

Theophylline products may cause dysrhythmia and/or worsen preexisting arrhythmias and any significant change in rate and/or rhythm warrants monitoring and further investigation.

Studies in laboratory animals (minipigs, rodents, and dogs) recorded the occurrence of cardiac arrhythmias and sudden death (with histologic evidence of myocardial necrosis) when beta agonists and methylxanthines were administered concurrently. The significance of these findings when applied to humans is currently unknown.

PRECAUTIONS: General: On the average, theophylline half-life is shorter in cigarette and marijuana smokers than in nonsmokers, but smokers can have half-lives as long as nonsmokers. Theophylline should not be administered concurrently with other xanthine preparations. Use with caution in patients with hypoxemia, hypertension or with a history of peptic ulcer. Theophylline may occasionally act as a local irritant to the GI tract, although GI symptoms are more commonly centrally mediated and associated with serum drug concentrations over 20 µg/mL.

Information for Patients:

The physician should reinforce the importance of taking only the prescribed dose at the prescribed time intervals. The patient should alert the physician if symptoms occur repeatedly, especially near the end of a dosing interval. When prescribing administration by the sprinkle method, details of the proper technique should be explained to the patient.

Laboratory Test: Serum levels should be monitored periodically to determine the theophylline levels associated with observed clinical response and to identify the potential for toxicity. For such measurements, the serum sample should be obtained at the time of peak concentration, approximately 5-9 hours after the morning dose. It is important that the patient has not missed or taken additional doses during the previous 48 hours and that dosing intervals have been reasonably equally spaced.

DOSE ADJUSTMENT BASED ON SERUM THEOPHYLLINE MEASUREMENTS WHEN THESE INSTRUCTIONS HAVE NOT BEEN FOLLOWED MAY RESULT IN RECOMMENDATIONS THAT PRESENT RISK OF TOXICITY TO THE PATIENT.

Drug Interactions:

Drug-Drug: Toxic synergism with ephedrine has been documented and may occur with some other sympathomimetic bronchodilators. In addition, the following drug interactions have been demonstrated:

Theophylline with:	Increased serum theophylline levels
Allopurinol (high dose)	Increased serum theophylline levels
Cimetidine	Increased serum theophylline levels
Erythromycin, Troleandomycin	Increased renal excretion of lithium
Lithium carbonate	Increased serum theophylline levels
Oral contraceptives	Decreased theophylline and phenytoin serum levels
Phenytoin	Decreased serum theophylline levels
Rifampin	

Drug-Food: Taking Slo-bid immediately after a high-fat content meal such as 8 ounces whole milk, 2 fried eggs, 2 strips bacon, one bran muffin with butter, 2 ounces hash brown potatoes (about 750 calories, including approximately 49 gm of fat) may result in a decrease in the rate of absorption, but with no significant difference in the extent of absorption (see CLINICAL PHARMACOLOGY, Pharmacokinetics). The influence of the type and amount of other foods, as well as the time interval between drug and food, has not been studied.

Drug/Laboratory Test Interactions: Currently available analytic methods, including high-pressure liquid chromatography and immunoassay techniques, for measuring serum theophylline levels are specific. Metabolites and other drugs generally do not affect the results. Other new analytic methods are also now in use. The physician should be aware of the laboratory method used and whether other drugs will interfere with the assay for theophylline.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Long-term carcinogenicity studies have not been performed with theophylline.

Chromosome-breaking activity was detected in human cell cultures at concentrations of theophylline up to 50 times the therapeutic serum concentrations in humans. Theophylline was not mutagenic in the dominant lethal assay in male mice given theophylline intraperitoneally in doses up to 30 times the maximum daily human oral dose.

Studies to determine the effect on fertility have not been performed with theophylline.

Pregnancy: Pregnancy Category C.—Animal reproduction studies have not been conducted with theophylline. It is also not known whether theophylline can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Theophylline should be given to a pregnant woman only if clearly needed.

Nursing Mothers: Theophylline is distributed into breast milk and may cause irritability or other signs of toxicity in nursing infants. Because of the potential for serious adverse reactions in nursing infants from theophylline, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use:

Safety and effectiveness of Slo-bid Gyrocaps administered:

1. Every 24 hours in children under 12 years of age, have not been established.
2. Every 12 hours in children under 6 years of age, have not been established.

ADVERSE REACTIONS: The following adverse reactions have been observed, but there has not been enough systematic collection of data to support an estimate of their frequency. The most consistent adverse reactions are usually due to overdose.

Gastrointestinal: nausea, vomiting, epigastric pain, hematemesis, diarrhea.

Central Nervous System: headaches, irritability, restlessness, insomnia, reflex hyperexcitability, muscle twitching, clonic and tonic generalized convulsions.

Cardiovascular: palpitation, tachycardia, extrasystoles, flushing, hypotension, circulatory failure, ventricular arrhythmias.

Respiratory: tachypnea.

Renal: potentiation of diuresis.

Other: alopecia, hyperglycemia, inappropriate ADH syndrome, rash.

CAUTION: Federal (U.S.A.) law prohibits dispensing without prescription. Keep this and all medications out of the reach of children.

NOW SUPPLIED: Slo-bid Gyrocaps are identified as follows:

- 50 mg—Clear (cap) and opaque white (body) capsule with 50 printed in red
- 75 mg—Opaque white (cap) and clear (body) capsule with 75 printed in red
- 100 mg—Clear capsule with 100 printed in red
- 125 mg—Opaque white (cap) and opaque white (body) capsule with 125 printed in red
- 200 mg—Opaque white (cap) and clear (body) capsule with 200 printed in red
- 300 mg—Opaque white capsule with 300 printed in red

Slo-bid Gyrocaps 50 mg are available in bottles of 100 (NDC 0075-0057-00), bottles of 1000 (NDC 0075-0057-99) and in unit dose 10 x 10 (NDC 0075-0057-62). Slo-bid Gyrocaps 75 mg are available in bottles of 100 (NDC 0075-1075-00), bottles of 1000 (NDC 0075-1075-99) and in unit dose 10 x 10 (NDC 0075-1075-62). Slo-bid Gyrocaps 100 mg are available in bottles of 100 (NDC 0075-0100-00), bottles of 1000 (NDC 0075-0100-99) and in unit dose 10 x 10 (NDC 0075-0100-62). Slo-bid Gyrocaps 125 mg are available in bottles of 100 (NDC 0075-1125-00), bottles of 1000 (NDC 0075-1125-99) and in unit dose 10 x 10 (NDC 0075-1125-62). Slo-bid Gyrocaps 200 mg are available in bottles of 100 (NDC 0075-0200-00), bottles of 1000 (NDC 0075-0200-99) and in unit dose 10 x 10 (NDC 0075-0200-62). Slo-bid Gyrocaps 300 mg are available in bottles of 100 (NDC 0075-0300-00), bottles of 1000 (NDC 0075-0300-99) and in unit dose 10 x 10 (NDC 0075-0300-62), and are manufactured by:

**Now, MDI therapy
is available to more patients
than ever before**

AeroChamber®
WITH MASK (aerosol holding chamber)

Permits easier metered-dose inhaler (MDI) therapy in children and the elderly (see boxed statement below). The device consists of an aerosol holding chamber with a soft, flexible mask that covers the patient's nose and mouth. A one-way valve holds the medication until the patient inhales. Expired air is vented through exhalation ports. AeroChamber with Mask is economical and fits virtually any inhaler.

IMPORTANT INFORMATION

Package insert dosing instructions should be consulted for all metered-dose inhalers (MDIs) when used with AeroChamber with Mask.

Dosage and administration recommendations vary for different MDIs, and the limitations and conditions of use for each product should be considered before utilizing this device, particularly for younger and older patients.

CARNATION.

GOOD NATURE™

Iron Fortified Follow-Up Formula

For babies over six months of age
eating solid foods

When baby reaches the solid food stage, approximately 6 months of age, formula is no longer his sole source of nutrition. Yet, whole milk* doesn't contain all the necessary vitamins and the high-carbohydrate cereals, fruits, and vegetables he eats are low in certain nutrients. And, older babies require less energy from fat¹ and more from protein².

Carnation.

GOOD NATURE™ Follow-Up Formula provides the added nutrients for the older baby's optimal growth and development. And it contains

more protein and calcium than starter formula to support the increased metabolic demands of bone mineralization and muscle mass growth.

The ratio of unsaturated to saturated fatty acids in GOOD NATURE is 2:1. GOOD NATURE is higher in monounsaturated fatty acids yet contains 28% less fat than starter formula to satisfy the changing needs of the older baby.

GOOD NATURE also has a carbohydrate blend of 63% corn syrup solids and 37% lactose to help assure tolerance. It contains 12 mg iron per quart to help ensure a sufficient supply at an age when inborn stores are depleted. GOOD NATURE costs less than starter formula and also tastes, smells, and looks like the real food baby is learning to enjoy.

When baby is ready for solid food, Mom may ask you about GOOD NATURE Follow-Up Formula. You can reassure her that GOOD NATURE is nutritionally sound and makes good sense for her baby.

For more information about GOOD NATURE Follow-Up Formula, please write to:
Carnation Nutritional Products,
5045 Wilshire Blvd., Los Angeles, CA 90036.

Carnation.
*Setting the stage
for better development™*

GOOD NATURE Follow-Up Formula...
now available to consumers in
32-fl-oz ready-to-feed fresh packs
and 12-oz easy-to-mix powder canisters.

Radiological Cases of the Month

Alain Martinot, MD; Francis Leclerc, MD; Martine Remy-Jardin, MD; Jean Darras, MD;
Michel Chenaud, MD; Lionel Wattinne, MD (*Contributors*); Beverly P. Wood, MD (*Section Editor*)

Figure 1.

Figure 2.

Figure 3.

A previously healthy 12-month-old girl had a 3-day history of fever (temperature, 40°C), sore throat, dysphagia, and vomiting. Physical examination revealed 2 × 3-cm left cervical adenopathy and hepatosplenomegaly. No focal infection was identified.

Admission chest roentgenogram was normal. White blood cell count was $12.5 \times 10^9/L$ (0.52 neutrophils); C-reactive protein level was elevated (294 mg/L). Cerebrospinal fluid and

urinalysis findings were normal. Three blood cultures yielded *Staphylococcus aureus*, methicillin sodium-susceptible.

Despite antibiotic treatment with vancomycin hydrochloride, rifampin, and amikacin sulfate, she remained febrile with positive blood cultures for 3 days. There was no dyspnea or dysphagia. On the third day after admission, a chest roentgenogram was abnormal (Fig 1). A left posterior oblique

chest roentgenogram (Fig 2) and lateral neck roentgenogram (Fig 3) with barium swallow were obtained.

Accepted for publication October 20, 1988.

Contributed from the Departments of Pediatrics (Drs Martinot, Leclerc, and Chenaud), Otorhinolaryngology (Dr Darras), and Radiology (Drs Remy-Jardin and Wattinne), Centre Hospitalier Universitaire de Lille (France), Hôpital Calmette.

Reprint requests to Department of Radiology, PO Box 648, University of Rochester Medical Center, 601 Elmwood Ave, Rochester, NY 14642 (Dr Wood).

Denouement and Discussion

Extrapleural Effusion of Retropharyngeal Origin

Fig 1.—Posteroanterior chest roentgenogram showing a left extrapleural opacity (arrow) widening the upper mediastinum.

Fig 2.—Left posterior oblique chest roentgenogram with barium in the esophagus showing a left mediastinal/extrapleural opacity and narrowing of the esophagus in the upper thorax (arrow).

Fig 3.—Lateral neck roentgenogram showing increased width of the retropharyngeal soft tissues (R), reversal of the cervical spine lordosis, and anterior displacement of the upper esophagus.

The diagnosis of cervicoextrapleural and cervicomediastinal extension of a retropharyngeal abscess was suspected. With the patient under general anesthesia, the posterior pharyngeal wall appeared normal, but digital palpation revealed a fluctuant mass. A large amount of purulent material was drained by incision of the posterior pharyngeal wall, and the next day chest and lateral neck roentgenograms showed resolution of both the extrapleural and mediastinal effusions and disappearance of the retropharyngeal thickening. Antibiotic treatment was discontinued after 21 days, and the patient was discharged in good health.

Downward propagation via the retrovisceral space of a retropharyngeal abscess is extremely rare since the advent of antibiotics.¹⁻³ This retrovisceral space is the major pathway of oropharyngeal infection spread to the neck and mediastinum.¹ Behind the esophagus and anterior to the prevertebral fascia, the retrovisceral space

extends upward to the base of the skull and inferiorly into the posterior mediastinum. The cervical space is in continuity with the retropharyngeal space through the thin alar fascia. At the thoracic inlet there is anatomic correspondence with Sibson's fascia, a tent-shaped layer attached to the lower cervical spine and upper ribs, which allows extrapleural spread of an abscess.

The diagnosis of retropharyngeal abscess may be difficult in very young children.⁴ In this patient, dysphagia disappeared rapidly after admission and there was no respiratory difficulty, noisy breathing, or visible swelling of the posterior pharyngeal wall. Cervical lymphadenopathy suggested the diagnosis. Lateral neck views were obtained and barium swallow was performed because of the noted widening of the upper mediastinum.

Recommendations follow:

1. In cases of retropharyngeal abscess, a search for cervicoextrapleural and cervicomediastinal extension by

repeated chest roentgenograms should be performed. Computed tomographic scan with contrast will differentiate between cellulitis and abscess and identify the site and extent of abscess formation.

2. In cases of unexplained upper thoracic extrapleural effusion or widened mediastinum, one must search for a retropharyngeal abscess even in the absence of dysphagia, dyspnea, or swelling of the posterior pharyngeal wall. Lateral neck roentgenography, computed tomography, barium swallow, and ultrasound are the best procedures to detect a retropharyngeal abscess.⁴

A 3-week-old male infant was seen for routine evaluation. His parents reported no problems other than decreased

feeding for 4 to 5 days. The infant was mildly pale and tachypneic. His weight was 3700 g (60 g above birth weight). Respirations were 70/min. There was a grade 2/4 systolic ejection murmur at the upper left sternal border. Pulses were normal. He was referred for further diagnostic studies, including a chest roentgenogram (Fig 1), an echocardiogram (Fig 2), magnetic resonance imaging (Fig 3), and angiography (Fig 4).

Accepted for publication October 20, 1988.

Figure 1.

Figure 2.

Figure 3.

Anomalous Origin of the Right Pulmonary Artery From the Aorta: 'Hemitruncus'

Fig 1.—Chest roentgenogram showing cardiomegaly with prominent main pulmonary artery segment (arrow) and increased pulmonary vascular markings, more prominent on the right side than on the left side.

Fig 2.—Two-dimensional echocardiogram. Suprasternal notch view shows the right pulmonary artery (P) arising posteriorly from the ascending aorta (A).

Fig 3.—Magnetic resonance image in sagittal plane (top) and axial plane (bottom) demonstrating the origin of the right pulmonary artery (P) from the aorta (A). The axial plane image also demonstrates the left pulmonary artery (arrow) and its attachment to the main pulmonary trunk.

Fig 4.—Main pulmonary arteriogram demonstrates the continuity of the main pulmonary trunk (P) with the left pulmonary artery (L). The catheter balloon tip is inflated in the patent ductus arteriosus, obstructing the flow of contrast into the aorta.

Hemitruncus is an unusual cardiovascular malformation in which one pulmonary artery, usually the right,¹ arises from the ascending aorta, while the opposite pulmonary artery connects normally to the main pulmonary trunk. An associated patent ductus arteriosus is common,² and intracardiac defects are occasionally present.^{1,2} The diagnosis must be applied cautiously to avoid confusion with conditions in which one pulmonary artery is absent and circulation to that lung is supplied via a systemic collateral vessel.¹

As a result of this anatomic malformation, systemic venous return in its entirety is directly through a single pulmonary artery, usually the left, while the contralateral lung is perfused with systemic arterial blood (a left-to-right shunt).¹⁻⁵ Pulmonary hypertension is present in both lungs, but the pathologic abnormality of the small pulmonary arteries may differ on the two sides.⁶ Embryologically, the defect is felt to result from defective development of the conotruncal ridges.^{1,3}

The condition manifests in infancy with signs and symptoms of congestive heart failure. The plain chest roentgenogram may not suggest the diagnosis. Radionuclide angiography

Figure 4.

is helpful.⁷ Computed tomography,⁸ echocardiography,^{9,10} and magnetic resonance imaging may all be diagnostic. Cardiac catheterization and angiography are performed for the assessment of hemodynamics and the exclusion of associated defects.

Treatment consists of relocation of the anomalous pulmonary artery from the aorta to the pulmonary trunk, either directly or with the use of a graft.¹⁻³ Surgery should be performed promptly in infancy for the alleviation of symptoms and the prevention of

progressive pulmonary vascular disease.

Tavist[®] Syrup
(clemastine fumarate) 0.67 mg/5 ml

**Lets kids be kids
12 hours long**

*National Prescription Audit, IMS America, Ltd. Data on file,
Sandoz Pharmaceuticals Corporation.

BRIEF SUMMARY

AVIST®

(clemastine fumarate) SYRUP 0.5 mg/5 ml
(present as clemastine fumarate 0.67 mg/5 ml)

INDICATIONS AND USAGE

Tavist® (clemastine fumarate) Syrup is indicated for the relief of symptoms associated with allergic rhinitis such as sneezing, rhinorrhea, pruritus and lacrimation. Tavist® (clemastine fumarate) Syrup is indicated for use in pediatric populations (age 6 years through 12) and adults (see **DOSAGE AND ADMINISTRATION**).

It should be noted that Tavist® (clemastine fumarate) is indicated for the relief of mild, uncomplicated allergic skin manifestations of urticaria and angioedema at the 2 mg dosage level only.

CONTRAINDICATIONS

Antihistamines are contraindicated in patients hypersensitive to the drug or to other antihistamines of similar chemical structure (see **PRECAUTIONS — Drug Interactions** in a complete package insert).

Antihistamines should not be used in newborn or premature infants. Because of the higher risk of antihistamines for infants generally and for newborns and premature infants in particular, antihistamine therapy is contraindicated in nursing mothers (see **PRECAUTIONS — Nursing Mothers** in a complete package insert).

WARNINGS

Antihistamines should be used with considerable caution in patients with: narrow angle glaucoma, stenosing peptic ulcer, pyloroduodenal obstruction, symptomatic prostatic hypertrophy, and bladder neck obstruction.

Use with CNS Depressants: Tavist® (clemastine fumarate) has additive effects with alcohol and other CNS depressants (hypnotics, sedatives, tranquilizers, etc.).

Use in Activities Requiring Mental Alertness: Patients should be warned about engaging in activities requiring mental alertness such as driving a car or operating appliances, machinery, etc.

Use in the Elderly (approximately 60 years or older): Antihistamines are more likely to cause dizziness, sedation, and potentiation in elderly patients.

ADVERSE REACTIONS

The most frequent adverse reactions are underlined:

Nervous System: Sedation, sleepiness, dizziness, disturbed coordination, fatigue, confusion, restlessness, excitation, nervousness, tremor, irritability, insomnia, euphoria, paresthesia, blurred vision, diplopia, vertigo, tinnitus, acute labyrinthitis, hysteria, neuritis, convulsions.

Gastrointestinal System: Epigastric distress, anorexia, nausea, vomiting, diarrhea, constipation.

Respiratory System: Thickening of bronchial secretions, tightness of chest and wheezing, nasal stuffiness.

Cardiovascular System: Hypotension, headache, palpitations, tachycardia, extrasystoles.

Hematologic System: Hemolytic anemia, thrombocytopenia, granulocytosis.

Genitourinary System: Urinary frequency, difficult urination, urinary retention, early menses.

General: Urticaria, drug rash, anaphylactic shock, photosensitivity, excessive perspiration, chills, dryness of mouth, nose and throat.

DOSAGE AND ADMINISTRATION

DOSAGE SHOULD BE INDIVIDUALIZED ACCORDING TO THE NEEDS AND RESPONSE OF THE PATIENT.

Pediatric: Children aged 6 to 12 years

For Symptoms of Allergic Rhinitis — The starting dose is 2 teaspoonsful (0.5 mg clemastine) twice daily. Since single doses of up to 2.25 mg clemastine were well tolerated by this age group, dosage may be increased as required, but not to exceed 2 teaspoonsful daily (3 mg clemastine).

For Urticaria and Angioedema — The starting dose is 2 teaspoonsful (1 mg clemastine) twice daily, not to exceed 6 teaspoonsful daily (3 mg clemastine).

Adults and Children 12 Years and Over

For Symptoms of Allergic Rhinitis — The starting dose is 2 teaspoonsful (1 mg clemastine) twice daily. Dosage may be increased as required, but not to exceed 12 teaspoonsful daily (3 mg clemastine).

For Urticaria and Angioedema — The starting dose is 4 teaspoonsful (2 mg clemastine) twice daily, not to exceed 12 teaspoonsful daily (6 mg clemastine).

HOW SUPPLIED

Tavist® (clemastine fumarate) Syrup

Clemastine 0.5 mg/5 ml (present as clemastine fumarate 0.67 mg/5 ml). A clear, colorless liquid with a citrus flavor, in 4 fl. oz. bottle (NDC 0078-0222-31).

We target the physician you want!

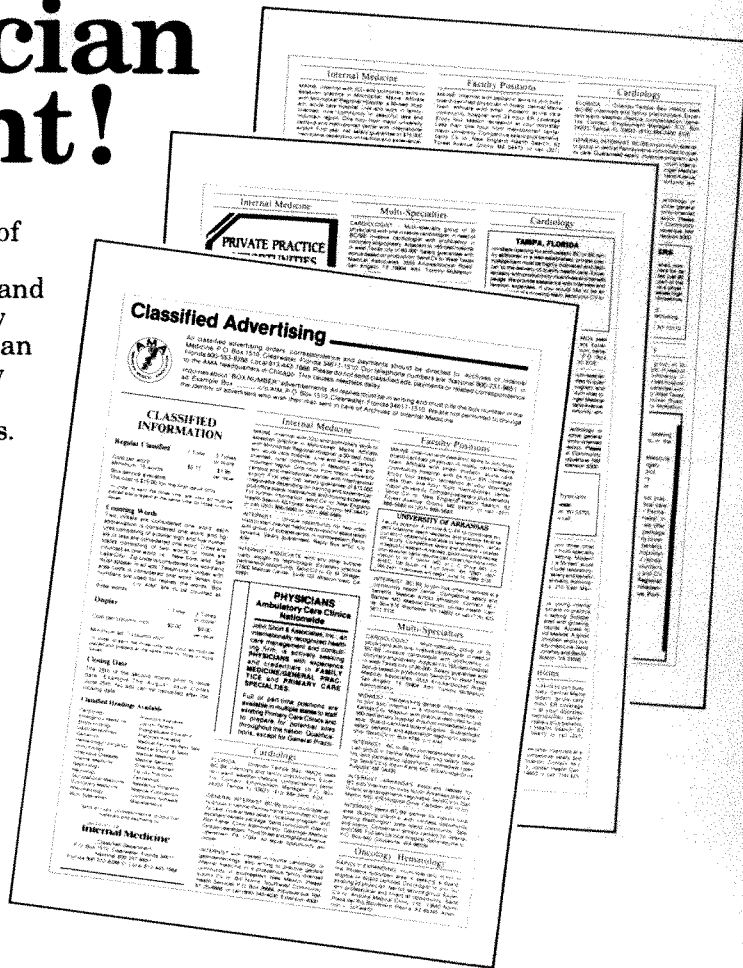

The AMA now offers a marketplace of opportunities in your own specialty journal. Starting in September, AJDC and all Archives journals will feature a new "Classified Advertising" section. You can put your message in the hands of every specialist in your target market, every month, with one or more AMA journals.

The affordable "Classified Advertising" section in each journal offers a highly visible concentration of wide-ranging physician opportunities within each specialty.

Take your choice, but make that choice an AMA specialty journal for physician recruiting. The reason: We target the physician you want to reach.

Short-term Memory Impairment in Cannabis-Dependent Adolescents

Richard H. Schwartz, MD; Paul J. Gruenewald, PhD; Michael Klitzner, PhD; Paul Fedio, PhD

• The concentration of Δ -9-tetrahydrocannabinol in marijuana available in the United States has increased by 250% since investigations of the effects of marijuana on short-term memory first appeared in scientific journals. Moreover, previous investigations of short-term memory in long-term marijuana smokers involved adults only. We evaluated the auditory/verbal and visual/spatial memory of 10 cannabis-dependent adolescents and compared the results with performance of 17 subjects in two control groups. The control groups included 8 adolescent drug abusers who had not been long-term users of cannabis and another 9 adolescents who had never abused any drug. All three groups were matched on age, IQ, and absence of previous learning disabilities. Adolescents with a history of frequent alcohol or phencyclidine abuse were excluded from entering the study. A

battery of seven neuropsychological tests was administered initially to all subjects and a parallel test battery was administered 6 weeks thereafter. Significant differences between the cannabis-dependent group and the two control groups were obtained initially on the Benton Visual Retention Test ($F[2,24] = 6.07$) and the Wechsler Memory Scale Prose Passages ($F[2,23] = 7.04$). After 6 weeks of supervised abstinence from intoxicants, subjects in the cannabis-dependent group showed some significant improvement on the Wechsler Memory Prose Passages score and on the Benton Visual Retention Test; however, the improvement failed to achieve statistical significance. We concluded that cannabis-dependent adolescents have selective short-term memory deficits that continue for at least 6 weeks after the last use of marijuana.

(AJDC. 1989;143:1214-1219)

ers were found to react more slowly on perceptuomotor tasks, such as the Pencil Tapping Test. When the scores of all the memory tests were combined, there was no difference between the score of the cannabis-dependent group and that of the control group. However, statistically significant differences were noted for the individual tests of short-term (recent) memory, with the cannabis-dependent individuals scoring much lower.

The potency of drug-quality cannabis has been steadily increasing, averaging 3.65% Δ -9-tetrahydrocannabinol (Δ -9-THC) in 1987 vs 1.5% Δ -9-THC a decade ago.¹⁵ Sinsemilla, the highly potent seedless variety of marijuana preferred by many users (including the cannabis-dependent teenagers in the present study), averages 7% Δ -9-THC; as such, it is approximately twice as potent as the hashish available in the United States.¹⁶ Given these trends alone, a reevaluation of the effects of long-term cannabis use on short-term memory seemed to us justified and long overdue. The need for such a study was, moreover, confirmed by personal observation.

The pilot study reported here differs in several important ways from past research efforts.^{16,17} Unlike most past studies, the current study focuses on an American middle-class adolescent population with at least 8 years of education. We had observed that cannabis-dependent adolescents who have just entered a drug-abuse treatment program experience difficulties in recalling newly learned program rules and traditions as well as remembering who said what in a large group therapy setting. These adolescents report that such deficiencies persist for at least 3 or 4 weeks after their last use of cannabis. Their observations were the immediate impetus for this study.

Studies of the effects of long-term cannabis use conducted during the late 1960s, 1970s, and early 1980s inconsistently demonstrated memory impairment.¹⁻¹² Efforts to evaluate possible short-term memory impairment in cannabis-dependent individuals always involved adult subjects, and were usually conducted in North African, Asian, Caribbean, or Central American countries. Investigations conducted in Egypt⁴⁻⁸ and India,⁹⁻¹² for example, found that cannabis dependence was associated with abnormal Bender Gestalt Test and/or Wechsler Memory Scale scores. Satz and colleagues,³ who studied 41 cannabis-dependent Costa Rican

adults and 41 matched controls, initially found no significant differences on seven tests of neuropsychological functioning, including the Wechsler Adult Intelligence Scale and the Benton Visual Retention Test. However, Page and coauthors,¹³ in conducting a follow-up study, retested 27 of the 41 original cannabis-dependent subjects and 30 of the 41 matched original controls and found that the majority of the former group demonstrated reduced capacity for sustained attention and significant impairment of short-term memory on three of the seven neuropsychological tests. The cannabis-dependent subjects also had slower rates of processing and performance on self-paced measures that required sustained attention.

Clinical reports of the negative effects of long-term marijuana use on performance of skilled tasks and on motivation continue to appear in the literature. Varma and coworkers¹⁴ administered a battery of 13 psychological tests to 26 cannabis-dependent Indian adults and 26 matched controls. The cannabis use-

STUDY DESIGN AND PATIENT POPULATION

Patient Population

The 10 study subjects and 8 of the 17 controls were drawn from patients enrolled in a modified outpatient therapeutic community drug-abuse treatment program for adolescents in suburban Washington, DC. Participants were primarily white, middle-class adolescents whose median age was 16 years. A large majority were residing with their parents before entering the treatment facility and were convinced by parental pressure to enter treatment for chemical dependency. During the first 90 days after entering treatment, the patients remained in the facility during the day and early evening. They ate dinner and slept at the home of another adolescent in treatment who, because of his or her progress in the program, has earned trusted status. The average duration of stay in the treatment facility is 14 to 15 months. The parents of the subjects and those of the adolescents in the two control groups in our study were representative of those of other program participants. They are typically well educated (approximately 50% of the fathers hold college degrees), and many have professional or administrative jobs.

Inclusion Criteria

Criteria for inclusion in the study were (1) age 14 through 16 years; (2) an IQ between 90 and 125; (3) absence of childhood learning disabilities or hyperactivity, as determined by queries to participants, their parents, and a review of a photocopy of the sixth-grade report card; (4) alcohol intoxication less than weekly before entering the treatment facility and no record of chronic alcohol intoxication; (5) infrequent use (no more than 15 times) of phencyclidine, which is believed to impair short-term memory in persons who smoke it frequently¹⁸; and (6) no history of a prior seizure disorder, concussion, or psychosis.

No subject was taking any prescribed or illicit psychoactive medication during the study. Inclusion and exclusion criteria were verified by one of us (R.H.S.) after interviews with parents and receipt of photocopies of an upper elementary school report card.

Institutional Review Board Approval

Approval for this voluntary study was obtained from the Institutional Review Board of Georgetown University School of Medicine, Washington, DC. Oral and written consent was obtained from 27 participants and their parents. Withdrawal from the study was permitted at any time. Four cannabis-dependent subjects or their parents refused

to participate in the study, and 4 others who began the study were later excluded because their IQ scores fell outside study criteria.

Study Groups

A total of 27 participants met all study criteria. These 27 individuals represented three types of adolescents—cannabis-dependent adolescents (group A), drug-free adolescents (group B), and adolescent patients at the Straight Incorporated treatment facility, Springfield, Va, who had abused drugs but who had not been cannabis dependent (group C).

Group A.— Group A consisted of 10 adolescents (9 male, 1 female) admitted to the treatment facility between October 1985 and August 1986. Each of these individuals was interviewed by one of us (R.H.S.), and was found to fulfill *Diagnostic and Statistical Manual of Mental Disorders, Third ed*, criteria for cannabis dependence. All had smoked marijuana that they believed to be of high potency (mean, 18 g/wk) at least 4 days per week (mean, 5.9 d/wk) for at least 4 consecutive months—to within a few days of their admission to treatment (mean, 7.6 months). The 12-month prevalence of drinking alcoholic beverages to intoxication ranged from 0 to 35 times (mean, 19 episodes per year). Lifetime use of phencyclidine ranged from 0 to 15 times, with a mean use of 3.6 times.

Group B.— Group B consisted of nine adolescent volunteers (six males, three females), who were drug free. Adolescents in group B were individually interviewed in depth by a program staff member, and none had taken any drugs at any time with the possible exception of infrequent experimentation with alcohol, but not to drunkenness. They were matched to program participants in terms of socioeconomic status, home environment, parents' education, and IQ.

Group C.— Group C consisted of eight adolescents (three males, five females) admitted to the treatment facility during the study period. Although these individuals had experimented with many drugs, they had not smoked marijuana frequently enough to become dependent on it. They had smoked marijuana no more than 35 times in their lifetime. They smoked marijuana on average a few times a month and got drunk every 3 or 4 weeks. Use of other intoxicants, such as stimulant drugs or inhalants, was infrequent, and none of the young people was dependent on opiate drugs or cocaine.

Group C was included to control for the possible confounding effects on cognitive processing and concentration ability by emotional states of fear, anxiety, or depression possibly experienced by all adolescents immediately after entry into a treatment program. Group C also controlled to some de-

gree for premorbid personality differences between youth, who do and do not abuse drugs.

STUDY DESIGN

Urine Toxicology Tests

To ensure that study subjects remained drug free during the 6-week study period, periodic urine toxicologic tests were administered. The 18 drug-abusing participants furnished urine specimens twice a week under direct supervision from the date of entry into the treatment facility until the day of the retest. Specimens were provided by the drug-free members of group B every other week. Urine specimens were analyzed for cannabinoids and for other drugs within 7 days after collection by a licensed laboratory technologist using the Enzyme Multiplied Immunoassay Technique instrument, Syva Co, Palo Alto, Calif.¹⁹

Neuropsychological Test Battery

A battery of seven neuropsychological tests (Table 1) was administered to study subjects by one of two experienced neuropsychologic technicians under the close supervision of a licensed neuropsychologist from Georgetown University Hospital. To ensure validity, the testers were initially observed by their mentor as they administered the entire battery to three pilot subjects in the same treatment facility. The testing procedure and the scoring system were matched against those of the neuropsychologist, and close agreement was reached. The tests included a full-scale score, the digit span, and verbal and performance subtests on the Wechsler Intelligence Scale for Children, as well as six standardized tests selected to measure auditory/verbal and visual/spatial immediate and short-term (delayed) memory and praxis (construction ability). To minimize interference effects, verbal and nonverbal tests were alternated. This alternation of a verbal test followed by an auditory test helped assess delayed recall in one modality before presentation of further material in that same sensory modality.

The neuropsychologic technicians were ignorant of the group to which the participants had been assigned. To further ensure objectivity, the nine adolescents in group B appeared for the assessments without their usual jewelry, in keeping with the strict rules enforced on the adolescents in the program who constituted groups A and C.

For the groups in the program (groups A and C), the first test session was conducted between day 2 and day 5 (mean, day 2.5) of the adolescent's residence in the treatment facility. We chose those days to allow for dissipation of any obvious short-term effects of cannabis intoxication on cognition and

Table 1.—Memory Tests Administered to Study Subjects

Test	Notes and Comments
Peterson-Peterson Short-Term Memory Paradigm	Four words are presented at the rate of 1 word/s. Subject is distracted by being asked to count backward by three. After a 15- or 30-s delay the subject is asked to recall all four words. The score represents the number of recalled four-word sets in 10 s.
Buschke Selective Remembering Test	A list of 12 words are presented and the subject is asked to remember as many as possible immediately, and after a 30-s delay. The 12-word list is repeated by the examiner after every unsuccessful trial up to three trials. The score is the number of trials until a perfect 12 is obtained. A good score is 12 of 12 words by the third trial. Storage, retention, and retrieval of memory are tested.
Benton Visual Retention Test	One card containing two or more simple geometric designs in close proximity is viewed for 10-s and then hidden from sight. The subject is asked to draw from memory each of a series of 10 such cards immediately after a 10-s viewing and again after a 15-min delay. A good score is at least eight figures reproduced without significant errors of omission, addition, distortion, rotation, size, or misplacement.
Wechsler Memory Scale Prose Passages	Two prose passages (each containing 22 to 24 memory units) are read and the subject is asked to recall the passages word for word—immediately, and again after a 30-min interval. The score is the number of correct responses in passages A + B divided by 2.
Complex figure drawing	The subject views a figure drawing containing 18 components. The designs are copied directly and then by recall after a 30-min delay. Either the Rey-Osterrieth or the Taylor figures are used.
Paired Associate Learning Test	The subject listens to a list of 10 paired word associates of increasing complexity. The score consists of the total number of difficult pairs recalled immediately and after a 30-min delay.

memory. For group B, the first test session was scheduled at the subject's and technician's convenience.

Six weeks after the initial assessment, each subject served as his/her own control and retook a parallel form of the same test battery. The 6-week interval was chosen by one of us (R.H.S.), who believed that memory impairment reported to him by other cannabis-dependent patients seemed to improve after the first 4 to 6 weeks of abstinence. Parallel test forms were used by the testers to control for "practice effects" from the initial test to the retest 6 weeks later. By random selection, 50% of the subjects in each group were given battery A at the initial test and battery B at follow-up, while the other half took the parallel test batteries in the reverse order.

RESULTS

Urine Toxicology Results

Eight of the 10 cannabis-dependent adolescents (group A) had cannabinoid-positive urine specimens on the day of admission to the facility and continued to have cannabinoid-positive urine specimens for a mean of 3.75 days (range, 2 to 9 days). The remaining two cannabis-dependent adolescents did not have marijuana metabolites in the initial or subsequent urine specimens. We later determined that the cutoff point (100 ng/mL) used to test for urinary cannabinoids in this study was too high and as

such could be expected to fail to detect 25% of true-positive urine specimens.²⁰ The groups receiving treatment (groups A and C) were under constant surveillance, and any use would have been noted. To the extent that undetected use occurred in group B, such use would serve to *decrease* any cognitive differences that might be observed among the groups. By the second neuropsychological test session, all subjects in group A had long since been completely detoxified. None of the individuals in group B or group C had cannabinoid-positive urine at any time during the study.

School Report Card Grades

Report cards from sixth grade were reviewed to elicit a measure of academic performance before the onset of drug use. Photocopies of report cards were received from 80% of the members of groups A and C; average grade was B-, although one subject each in those two groups had a D average. Review of comments from the teacher confirmed the absence of hyperactivity or specific learning disability. Only three report cards were received from group B members; hence, no analysis was performed for this group.

Neuropsychological Test Battery Results

The neuropsychological data were analyzed using a series of two-way multivariate repeated-measures analyses of variance, with "group" and "test session" as main effects. (Within each memory test, a number of dependent measures were available for each analysis. For example, in the Wechsler Memory Prose Passage Test, measures were available of performance from two prose passages for immediate and delayed recall conditions. These four dependent measures were analyzed as a group. For all other tests, similar multiple dependent measure analyses were performed. The use of multiple indicators helps ensure the validity of the outcomes.) These analyses enabled us to test for the significance of overall group differences and for improvements in performance between the first and second test session. They also allowed us to test for a differential "return" (improvement) between groups over trials. In testing for this anticipated improvement, we expected a significant group \times test session interaction. That is to say, we believed that members of group A would improve substantially on any of the tests from which results had initially been poor. The repeated-measures tests (use of a test-retest research design) in these analyses helped to improve the statistical robustness because each subject served as his or her own control.²¹ These analyses reduced the likelihood of type I errors in this study. The criterion for significance was established at a moderately strict level of $P < .01$.²²

Additional preliminary analyses revealed that the three study groups did not significantly differ in terms of either verbal or performance IQ scores (Wilks' lambda = .682; $F[4,46] = 2.43$; $P = .061$), or age ($F[2,24] = 2.07$; $P = .149$). The mean full-scale IQ for the 10 cannabis-dependent adolescents (group A) was 108, vs 114 for the 17 controls (groups B and C). The mean age for the 10 cannabis-dependent adolescents was 16.0 years vs 15.3 years for the 17 controls.

Table 2 summaries of the results of the multivariate analyses of variance performed on the data from the seven memory tasks. There were significant differences between groups on two

†Test remains significant at $P < .01$ when males are examined separately.

Fig 1.—Comparison of Benton Visual Retention Test scores soon after admission and 6 weeks later.

tests of short-term memory. The cannabis-dependent group (group A) committed more errors on the Benton Visual Retention Test and scored lower than the controls on the Wechsler Memory Prose Passages Test. The cannabis-dependent group did not improve statistically across time on any of the memory tests compared with the control groups.

Figure 1 presents the average number of errors for subjects within each of the three groups on the Benton Visual Retention Test, immediate recall condition. Figure 2 presents scores for the three groups on the Wechsler Memory Prose Passages Test. There is some indication of "return" for group A, the

cannabis-dependent group, in both tasks; however, as noted above, it is not large enough to provide a statistically significant repeated-measures effect.

There were substantial differences, however, in the distribution of male and female adolescents among groups. Nine of 10 subjects in group A, 6 of 9 in group B, and 3 of 8 in group C were male. Supplemental data analyses were performed to determine the effect of gender on reliability of data relating to short-term memory by using analyses of covariance, and by analyzing male adolescents separately from female adolescents (there was an insufficient number of female adolescents to per-

form the complementary analysis). Results of these analyses supported all but one of the findings. Significant group differences were maintained for both the Benton Visual Retention Test ($F[2,23]=6.39$; $P=.01$) and the Wechsler Memory Prose Passages task ($F[2,22]=6.90$; $P=.01$) when the effects of gender were statistically controlled and when males were analyzed separately ($F[2,15]=7.24$; $P=.01$ and $F[2,14]=5.93$; $P=.01$, respectively).

Pairwise comparisons among the groups in the Benton Visual Retention task showed that the cannabis-dependent group (group A) committed significantly more errors on the first testing session than group C ($F[4,21]=3.51$; $P=.02$). This difference was restricted to the pretest only, where significant differences were obtained for both immediate ($F[1,24]=12.49$; $P=.01$) and delayed ($F[1,24]=6.38$; $P=.02$) recall conditions. On the posttest, no significant differences appeared for either immediate ($F[1,24]=.42$; $P=.52$) or delayed ($F[1,24]=3.64$; $P=.07$) recall conditions. Since the likelihood of type I errors in these tests is protected by the significant overall test statistic, the criterion of significance for these contrasts was $P=.025$.²¹ Pairwise comparisons between the groups in the Wechsler Memory Prose Passages task showed that the cannabis-dependent group (group A) scored significantly lower than group C ($F[8,16]=3.91$; $P=.01$). For immediate and delayed recall, this difference appeared in both the pretest and posttest conditions. For example, using scores for the immediate recall condition for memory passage A from the test, significant differences were found between the groups both at pretest ($F[1,23]=5.47$; $P=.03$) and posttest ($F[1,23]=11.45$; $P=.01$).

COMMENT

This pilot study provided evidence of the lingering impact of heavy marijuana use on selected short-term auditory and visual memory processes. Although it was conducted in a methodologically more rigorous manner than many past efforts,^{16,17} some problems admittedly remained in the study design. Larger research efforts with at least 25 subjects in each group better matched for gender would have improved the results of our

Fig 2.—Comparison of Wechsler Memory Prose Passages score soon after admission and 6 weeks later.

study. Budgetary constraints and diminished cooperativeness of the directors of the drug treatment facility obstructed the continuance of this study. We reluctantly were forced to halt the study after 27 eligible participants were enrolled.

Because the sample sizes of the groups were small, particular importance was placed on an examination of the distributions of the dependent measures. All were tested to determine if they differed significantly from normal. Three of the 21 measures used in the analyses did so; however, the particular form of the divergence from normality did not bias the result.²³ Thus, these measures were retained in their original form. Our original hypothesis was that we would demonstrate short-term memory loss in cannabis-dependent adolescents and that we would find normalization of such memory after 6 weeks. Our surprise at finding that the memory defects persisted at the 6-week retest occurred too late to modify the protocol and retest at a later date. In retrospect, additional tests of short-term memory should have been admin-

istered between 3 and 6 months after the 6-week testing session. Such repeated testing, if controlled for the "practice effect," might have demonstrated full return of any memory impairment and strengthened our hypothesis that marijuana was the main cause of the deficit. On the Wechsler Memory Prose Passages and the Benton tests, where differences between groups were observed on the initial test, there were no statistically significant "returns" in performance of the cannabis-dependent group over the 6 weeks of the study. Although Figs 1 and 2 suggest that such a return may occur, it does not appear significant ($P < .01$). The intergroup comparisons suggest that the observed differences between the cannabis-dependent group and the control groups may erode over the course of the 6 weeks in the case of the Benton Visual Retention Test; however, this finding is speculative in light of the absence of a corresponding overall significant repeated-measures effect. In the case of the Wechsler Memory Prose Passages task, significant differences were maintained between these groups through-

out the course of the study. These tasks represent two somewhat different types of information processing. The Benton Visual Retention Test requires the retention of visual information in iconic or unprocessed form over very brief periods, whereas the Wechsler Memory Prose Passages task requires the extraction of abstractions from complex stimuli (stories), encoding of these abstractions, retrieving information, and complex responding.

The failure to obtain significant differences between the cannabis-dependent group and the control group in the program may have been due to small sample sizes. Scores for the latter group were uniformly intermediate—falling between the former and the non-drug-dependent group. However, the failure to detect differences between groups A and C may also suggest that the common environments of the two groups (both appearing in the treatment program) may act to commonly alter scores on these tests.

Our current data provide little guidance on which to formulate hypotheses concerning the neurologic substrates of the observed results. Before such hypotheses may be meaningfully considered, studies should be conducted to elucidate which disruptions in what parts of the information processing system account for decreased performance. Such studies should use groups of subjects with matched gender ratios. Decreases in performance may be a function of decrements in attention, filtering, encoding, retrieval, and/or output. Isolation of the location and types of disruptions that account for the current results should, therefore, be one goal of future research in this area.

Although future research will further our understanding of the decrements we have observed, the current data have direct clinical implications. The results suggest the need to develop treatment strategies that incorporate the possibility of long-lasting cognitive deficits that may affect both performance of complex tasks and ability to learn. Results from investigations of Hawkins and coworkers²⁴ suggest that adolescents with learning disabilities are at high risk of cannabis abuse. The results reported here heighten our serious concerns about the effects of long-term

marijuana use on these already learning-impaired adolescents. For such individuals, regular use of marijuana, even to less of a degree than in our 10 study subjects, may significantly contribute to worsening school performance.

This investigation was funded in part by a grant from the Memorial and Endowment Fund of the American Academy of Pediatrics, Elk Grove Village, Ill, and by a gift from The Medical Trust of The Pew Memorial Trusts, Philadelphia, Pa.

Book Review

Management of Prader-Willi Syndrome, edited by L. R. Greenswag and R. C. Alexander, 324 pp, \$35, New York, NY, Springer-Verlag NY Inc, 1988.

This book is for all physicians, nutritionists, teachers, and other professionals who, in their work, encounter children with the Prader-Willi syndrome. The book is also an excellent resource for parents of such children.

Although one could learn how to make a diagnosis of the Prader-Willi syndrome by reading this book—Hans Zellweger has written a chapter in the book on differential diagnosis—the main thrust of the book is, as indicated in the title, the management of this difficult disorder. Medical management of hypogonadism, nutritional management of obesity, and therapeutic management of hypotonia are examples of issues pertinent to this condition that are discussed expertly and in detail.

Education, vocational training, and residential placement are other subjects covered in separate chapters. Psychological and behavioral management is discussed in one excellent chapter, but also sprinkled throughout the text is information on this crucial topic (eg, the stubbornness, food filching, and severe temper tantrums that are prominent symptoms in this disorder). The chapter on dental manifestation and management offers tips on how to deal with a child with Prader-Willi syndrome in the dental chair.

Several chapters deal with family issues. The chapter "Parents Point of View" gives practical advice, such as serving food so that portions look larger and helping children with an insatiable appetite who need less food than their

peers survive the school cafeteria. There are also good chapters on parent advocacy and networking.

Tables are used throughout this book to summarize important information. One useful table in the chapter on medical and nursing intervention lists all the major characteristics of the syndrome (as well as some minor ones like small hands and feet), their developmental sequence, and recommended intervention. Nine appendices cover a variety of subjects from syndrome-specific growth charts, food-exchange guidelines, and low-impact aerobic activity to postural control exercises (kyphoscoliosis is common in this syndrome) and summer camps.

I find little to argue with in this book. A four-page table on the nutrient content of multivitamins and mineral supplements might seem unnecessary. It is unfortunate that the old figure for recurrence rate (1.6%) has slipped into the chapter on genetics rather than the now accepted figure of 0.1%.

On the whole, however, this book is accurate, up to date, and timely. It provides much needed information not available elsewhere. *Management of Prader-Willi Syndrome* should be in the library of all professionals who minister to a child afflicted with this complex disorder.

Acquired Immunodeficiency Syndrome Among Adolescents

Case Surveillance Profiles in New York City and the Rest of the United States

Sten H. Vermund, MD, MSc; Karen Hein, MD; Helene D. Gayle, MD, MPH;
Joan M. Cary, MPH; Pauline A. Thomas, MD; Ernest Drucker, PhD

● **Adolescents engaging in certain sexual or drug-related behavior are at risk of contracting the human immunodeficiency virus infection in endemic locales. Local and national surveillance data were analyzed to determine the characteristics of the acquired immunodeficiency syndrome (AIDS) epidemic on adolescents. Of the 605 cases of AIDS in people aged 13 to 21 years reported through 1987, 518 were males (83 from New York City [NYC], NY), and 87 were females (28 from NYC). Over half of all adolescent males with AIDS reported homosexual contact. Transfusion/blood product-related human immunodeficiency virus acquisitions (especially in males with hemophilia) represented 11% of adolescent cases from NYC (1% of NYC adults) and 22% of adolescent cases in the United States (US) outside of NYC (4% of adults in the US). Intravenous drug use was more frequently reported among adolescents with AIDS from NYC (23%) than among adolescents outside NYC (14%). In females, heterosexual transmission accounts for about half of all adolescent AIDS cases and 29% of all adult cases. Age-appropriate services and behavioral interventions are urgently needed for high-risk adolescents.**

(AJDC. 1989;143:1220-1225)

Reported cases of the acquired immunodeficiency syndrome (AIDS) among adolescents aged 13 to 21 years account for 1.2% of the total number of AIDS cases in the United States (US).¹ Adolescents may acquire the human immunodeficiency virus (HIV) infection in sexual or intravenous (IV) drug-related interactions with infected adults and may then serve as a conduit of infection to other adolescents.^{2,3} Adolescents at highest risk for infection are likely to be disenfranchised youths, including runaways,^{4,5} youths engaged in prostitution,⁶ incarcerated youths,^{7,8} and IV drug users.^{9,10} Early age of first intercourse^{8,11-13} and multiple sexual partners¹⁰⁻¹⁵ may increase the risk of sexually transmitted diseases, which may, in turn, facilitate HIV transmission.^{7,16-18}

The current cocaine/crack epidemic among inner-city youths is occurring in the same urban areas with the highest HIV infection prevalence.⁹ Crack use may be associated with prostitution and with disinhibited, unsafe sexual relations. Intravenous cocaine may be used.¹⁵ Male homosexual youths report a greater sense of social isolation than their adult counterparts,¹¹ and they often have older sexual partners whose seroprevalence rates are likely to be higher than those of the adolescents' peer groups in HIV-endemic areas.¹¹ Finally, many people with severe hemophilia A, including adolescents, underwent transfusions prior to the spring of 1985 with nationally marketed, HIV-infected manufactured blood products.²⁰

The risk of HIV transmission among adolescents may be especially high in New York City (NYC), NY, where seroprevalence rates are estimated to be in the 9% to 22% range for males 25 to 44

years of age living in the South Bronx.²¹ As of mid-September 1988, over 16 600 cases of AIDS had been reported in NYC (23% of the total US cases).²² Over 200 000 people in NYC are believed to be infected with HIV.^{23,24} Adolescents in NYC who engage in needle sharing, unprotected anal intercourse, or coitus with people who have engaged in these behaviors are likely to be at greater risk of HIV infection than their peers who engage in high-risk activities in regions with lower HIV prevalence.²⁵ Some insight into transmission patterns of HIV infection can be inferred from AIDS surveillance data in the adolescent age group.^{21,26,27} This study describes characteristics of reported cases of AIDS in adolescents and compares adolescents from NYC with AIDS with adults from NYC with AIDS and adolescents with AIDS in the rest of the US.

METHODS

Surveillance data for AIDS from the Centers for Disease Control (CDC), Atlanta, Ga, and the NYC Department of Health from 1979 through 1987 were analyzed based on reports received through January 19, 1988. All reported cases of AIDS in adolescents aged 13 years and older that fulfilled the CDC adult case definition of AIDS in the US²⁸ were reviewed. Surveillance programs reporting to the CDC include the 50 states, Washington, DC, Puerto Rico, and island territories in the South Pacific and the Caribbean, including Guam, American Samoa, and the US Virgin Islands. Data included in this report are from the US, excluding Puerto Rico and the territories.

Case ascertainment by the NYC Department of Health was primarily derived from four sources.²⁹ Seventy percent of the cases were reported by hospital infection control officers, while 20% were reported directly by physicians to the Department of Health.

About 5% were detected by review of death certificates, and 1% to 2% were detected by CDC from investigational drug reports and medical records.³⁰

From data reported to CDC by state health departments, categories were created to describe the presumptive origins of transmission. For this report, we further grouped cases of AIDS into one of six transmission categories: (1) male homosexual or bisexual activity, (2) male homosexual or bisexual activity and IV drug use, (3) IV drug use, (4) heterosexual activity with IV drug use or bisexual activity, (5) receipt of a transfusion of blood or blood products, and (6) other or unknown behavior. Proportional frequencies for each transmission category were compared for NYC and the US excluding NYC. The CDC surveillance system is described in more detail elsewhere.²⁰

Surveillance data were compiled by age (pediatric, under 13 years of age; adolescent, from 13 through 21 years of age; and adult, over 21 years of age), sex, and date of diagnosis. Adolescents were defined as people aged 13 to 21 years to match the American Academy of Pediatrics' definition and the administrative organization of many adolescent health care programs. Pearson's χ^2 (with Yates' continuity correction for 2×2 tables) was used to determine the significance of between-group differences.³¹ To accommodate small numbers, the very small number of male heterosexual cases were combined with the male other/unknown cases and the few female blood product-related cases were combined with female other/unknown cases in statistical comparison of NYC adolescent AIDS case proportional frequencies with those of adolescents from elsewhere in the US.

RESULTS

Characteristics of Adolescents With AIDS

As of January 19, 1988, 605 (1.2%) of 51 334 reported AIDS cases in the US were in people 13 to 21 years of age; 518 were male and 87 were female (Table). While only 3% of the nation's 13- to 21-year-olds live in NYC, 20% of all reported US AIDS cases in this age range live in NYC. Thus, NYC accounted for 6% of the total AIDS cases reported in male adolescents in the US and 32% of the total AIDS cases reported in female adolescents in the US (Table). The frequency of AIDS in the adolescent age group rises markedly with increasing age. Half of the cases in the 13- to 21-year-old age category are seen in 20- and 21-year-olds, who would be expected to represent only about 22% of the 13- to 21-year-old age group

Age Range, y	Males		Females		Total (n = 51 334)	M:F Ratio	
	NYC	US	NYC	US		NYC	US
≤12	114	307	136	205	762	0.8	1.5
13-21	83	435	28	59	605	3.0	7.4
≥22	9903	36 426	1234	2404	49 967	7.1	15.2

Fig 1.—Cumulative prevalence of acquired immunodeficiency syndrome cases reported to the Centers for Disease Control, Atlanta, Ga, as of January 19, 1988, by 6-month periods from 1979 to 1987 for the United States. Adults are over 21 years of age, adolescents are 13 to 21 years of age, and children are under 13 years of age.

($P < .001$). The ratio of male adolescent to female adolescent cases is 3:1 in NYC and 7:1 in the US excluding NYC, while the adult ratio is 7:1 in NYC and 15:1 in the US excluding NYC (Table).

The rate of growth in the cumulative incidence of AIDS in the US has been rapid in the first 9 years of the AIDS epidemic (Fig 1). The reported onset of the epidemic in adults and children, as documented from surveillance reports, preceded the recognition of AIDS among adolescents who were retrospectively diagnosed in 1981 (Fig 1).

Adolescents Compared With Adults

Proportional frequencies of risk behavior associated with AIDS are different in adolescent and adult cases. Both in NYC (Fig 2) and in the US excluding NYC (Fig 3), adolescents with AIDS are proportionately less likely than adults with AIDS to have acquired the infection by male homosexual activity or IV drug use. Using data from the US including NYC (data from Figs 2 and 3 combined), adolescents with AIDS are comparatively more likely to have ac-

quired the infection from transfusion of blood products (20% among all adolescent cases compared with 3% among all adult cases) or from heterosexual transmission (9% among all adolescent cases compared with 4% among all adults) ($P < .0001$).

The preponderance of transfusion/blood products-acquired AIDS is largely among males, because of the many patients with hemophilia. The heterosexual proportional differences can be attributed to differences among female patients; 47% of AIDS cases in female adolescents and 29% of AIDS cases in female adults are reportedly due to heterosexual spread, while the comparable figure among males is 2% for both adolescents and adults.

Adolescents in NYC Compared With Adolescents in the Rest of the US

Among males, a history of IV drug use, with or without a history of homosexual activity, is reported in 16% of adolescent AIDS cases in NYC compared with 4% of adolescent AIDS cases from the rest of the US. Adolescents in

Fig 2.—Transmission profile for all adolescents aged 13 to 21 years with acquired immunodeficiency syndrome compared with adults over age 21 years with acquired immunodeficiency syndrome in New York City.

Fig 3.—Transmission profile for all adolescents aged 13 to 21 years with acquired immunodeficiency syndrome compared with adults over age 21 years with acquired immunodeficiency syndrome in the United States excluding New York City.

NYC and the US show a similar proportion of cases in males reporting homosexual/bisexual activity, from 55% to 57% of all adolescent AIDS cases (Fig 4). Transfusion-related cases are proportionately more common outside NYC. Proportional differences between cases in males in NYC and those from the rest of the US are significantly different from one another ($P < .0001$), indicating comparatively more drug use-related illness in NYC.

Proportionately more AIDS cases in female adolescents are IV drug use related and heterosexually acquired in NYC reports than in those from elsewhere in the US (Fig 5) ($P = .4$). As with male adolescents, few transfusion-related cases of AIDS are noted in female adolescents from NYC compared with those cases from elsewhere in the US. Overall differences between AIDS cases in female adolescents in NYC and in the rest of the US are not significant,

but the number of reported cases for female adolescents is small (Table).

COMMENT

Based on its population compared with the rest of the US, NYC accounts for more than six times the number of adolescent AIDS cases that would be expected if rates of AIDS were equal nationwide. Since characteristics of the epidemic differ for adolescents compared with adults, service needs are also likely to differ. For example, among adolescents with AIDS, there is a higher proportion of females than among adults with AIDS, both in NYC and in the rest of the US (Table). Since drug-related and sexually acquired cases of AIDS are proportionately more common among adolescents in NYC than elsewhere in the US, they are of special concern to health workers in NYC. The transfusion/blood product data do not suggest that the larger proportion of transfusion/blood product recipients among adolescents with AIDS outside NYC is due to higher rates of seroprevalence among persons with hemophilia. Rather, as infection rates among people with severe hemophilia A are quite similar nationwide,²⁰ people with hemophilia are a smaller proportion of the total AIDS cases in NYC than they are elsewhere in the US.

Several screening programs and seroprevalence studies have included adolescents. About 60 000 entrants, aged 16 to 21 years, to the residential training program of the Job Corps are being tested for HIV antibodies yearly.²⁰ Among these disadvantaged youth, 0.33% of the first 25 000 screened were HIV seropositive.²⁰ Military recruit applicants screened from October 1985 to July 1986 had a 0.4% seroprevalence rate in people aged 17 to 21 years.²² It is unlikely that adolescents seeking to enter the military represent youths currently at highest risk. Nevertheless, the rate ratios for HIV seroprevalence among male adolescents (13/4734, 0.3%) and female adolescents (4/854, 0.5%) reveal a relative female excess in the 17- to 21-year-old age group.²² Hence, this proportional excess risk for female adolescents compared with adults is apparent whether we are considering male-to-female ratios of reported AIDS cases, as described in the present report, or rate ratios of HIV positivity by

Fig 4. — Transmission profile for male adolescents aged 13 to 21 years with acquired immunodeficiency syndrome in New York City and the United States excluding New York City.

Fig 5. — Transmission profile for female adolescents aged 13 to 21 years with acquired immunodeficiency syndrome in New York City and the United States excluding New York City.

ex among military recruits. Human immunodeficiency virus seroprevalence among adolescents and young adults in NYC is the highest in the country among military recruit applicants.³³

A potential limitation in current surveillance data is underreporting of AIDS cases, particularly in low-prevalence groups or regions.³⁴ In NYC, case reporting is thought to be quite complete.^{29,30} Hence, unknown bias may enter national data that are based on a mix

of states, some of which have especially active AIDS case surveillance systems. The adolescents at highest risk often receive inadequate medical care and may be easily missed in case reporting for a number of conditions. Many of these youths may die from accidents, homicide, or suicide, which are the leading causes of death in this age group.³⁵ These competing causes of death and the inability of the current health care system to reach disenfranchised youth

may be contributing to an underestimation of adolescent AIDS cases. Given the much smaller number of cases overall among adolescents, such an undercounting, if it is occurring, would distort surveillance data far more than it would in the much larger adult case group.

Since only HIV-infected adolescents with rapid onset of AIDS³⁶ or those infected in their early teens will actually manifest signs or symptoms of AIDS by age 21 years, case reports of AIDS will inevitably underestimate the extent of the HIV epidemic among adolescents. Given the long latency of HIV infections, especially well documented among people who received transfusions on known dates,³⁷ relatively few infected adolescents will develop AIDS while still in the adolescent age group.

Higher rates of gonorrhea, syphilis, and hospitalization for pelvic inflammatory disease have been documented for sexually active adolescents than for sexually active adults.^{16,38} These differences may be due, in part, to physiologic or immunologic differences that occur during puberty which could facilitate the acquisition or spread of sexually transmitted diseases.^{16,38} It is possible that adolescents also have an increased risk of sexual transmission of HIV through the same unknown mechanisms.

A number of behavioral features related to adolescent sexuality are likely to increase the risk of HIV infection.^{2,3,7} The average age of first intercourse is 16 years in the US, though some subgroups (such as incarcerated youths) have a mean age of first intercourse as low as 12 years for both boys and girls.^{8,12,13} A substantial proportion of sexually active teenagers may have multiple sexual partners, with 41% of male adolescents and 23% of female adolescents reporting 17 or more sexual partners by age 19 years in one representative national sample.¹² In addition, female adolescents tend to have sexual partners who are, on average, 2 to 3 years older than they are.¹²

Male homosexual adolescents who have had intercourse report, on average, 7 partners by age 19 years.¹¹ The average age of their sexual partners is 7 years older than their own.¹¹ These factors may facilitate HIV sexual transmission from older infected persons to youth. High rates of unintended adolescent pregnancy continue in the 1980s,

particular among younger adolescents.¹³ Vertical transmission from an HIV-infected adolescent mother to her newborn offspring can occur.³⁸ Condom use is currently neither a popular nor a consistently used form of contraception among adolescents.^{13,14,40}

Reported drug use among a representative sample of high school seniors in the US from 1975 to 1986 reveals US rates to be the highest among the world's industrialized countries.⁴¹ While some decline in overall drug use is noted since the early 1980s, cocaine use among adolescents has remained relatively stable from 1979 to 1986. Current users, defined as people who used cocaine in any form in the preceding 30 days, represented 1.9% of seniors in the nationwide sample in 1975, 5.2% in 1980, and 6.7% in 1985,⁴¹ but fell to 4.3% in 1987 (Lloyd D. Johnston, PhD, Jerald G. Bachman, PhD, and Patrick M. O'Malley, PhD, unpublished data, January 12, 1988, University of Michigan press release). This recent trend among high school students is not particularly encouraging in relation to current patterns of reported adolescent AIDS cases.

In many inner-city neighborhoods high rates of crack use are continuing to rise.¹⁹ The substantial addictive potential of cocaine, especially in the form of crack,¹⁹ is likely to augment the risk of HIV transmission among adolescents in the inner-city neighborhoods of highest

HIV seroprevalence both by the practice of female and male prostitution to pay for or secure drugs and by possibly increasing IV drug use.^{9,17}

In addition, youth from minority backgrounds surveyed in San Francisco, Calif, and NYC have a poor fund of knowledge regarding the risk and prevention of AIDS.^{42,43} Expansion of drug prevention programs targeted toward teens and preteens, improved inner-city schools, more extensive youth job training programs, readily accessible adolescent health services focused on sexually transmitted diseases and birth control, and school-based sexual education with explicit AIDS-prevention training are all desirable.^{2,3,44} Education and training for AIDS prevention, screening and treatment programs for sexually transmitted diseases, and drug abuse prevention and treatment programs are the available means to reduce HIV transmission in the absence of a vaccine or adequate chemotherapy.^{45,46}

Given the growing number of AIDS cases among adolescents and young adults (Fig 1) and the long latency period from HIV infection to the onset of AIDS,^{36,37} seroprevalence studies are needed to measure the degree of HIV penetration into the adolescent age group. From previous experience with drug use and sexually transmitted diseases among adolescents, the spread of HIV infection is a major concern in this age group, particularly in areas of high

viral prevalence like NYC. Since adolescents are not a population with extensive experience in or resources for advocacy, community action, or self-help, it is particularly important that preventive, medical, and social services be designed by the public and private sectors to attract and retain youth. Strategies in risk reduction successfully developed among well-educated homosexual men with good peer support networks⁴⁶ may not be applicable to many adolescents at high risk.

There exists an urgent need for successful prevention and treatment models that will require community and school-based outreach and broad collaboration with those inner-city groups that have demonstrated an ability to communicate with disenfranchised youth. In the absence of a national effort to minimize the spread of HIV infection among vulnerable youth, particularly in the inner cities, the epidemic will likely expand within this age group.

This study was supported in part by the Samuel and May Rudin Foundation, the Fund for the City of New York, the Rockefeller Brothers' Fund, the Design Industries Foundation for AIDS, the New York Charitable Trust/Morgan Guaranty Trust Company, and the W. T. Grant Foundation, New York, NY.

Timothy J. Dondero, MD, and Martha F. Rogers, MD, CDC, and Stephen C. Joseph, MD, NYC Department of Health, facilitated this work. Cherie B. Boyer, PhD, James W. Curran, MD, Harold Jaffe, MD, and Nancy Reuben, MD, made useful suggestions. Dr Ralph Dell, Alison Greene, and Rosalyn Williams provided computer assistance. Barbara Aiken prepared the manuscript.

Septic Arthritis in Children With Hemophilia

Alberto S. Pappo, MD; George R. Buchanan, MD; Andrea Johnson, MSN, PNP

• Four of the 139 children with hemophilia followed up at our center have developed septic arthritis during the past 6 years (2.9% incidence). Two infections were caused by *Streptococcus pneumoniae* and one each by *Staphylococcus aureus* and *Haemophilus influenzae* type B. Common features at time of presentation included fever and a 2- to 7-day history of joint pain and swelling unresponsive to factor replacement infusions. Since three of the patients were human immunodeficiency virus seropositive, we propose that human immunodeficiency virus infection may be responsible for the disproportionately high number of cases of septic arthritis observed in our patient population.

(AJDC. 1989;143:1226-1228)

Infectious arthritis in children with hemophilia has been reported only rarely,¹⁻⁵ and just recently has it been suggested that joint infection is more prevalent among hemophiliacs than in the general population.¹ During the past 6 years, we have identified four cases of septic arthritis among hemophiliacs followed up in our center. During our review of the clinical and laboratory features of this complication, it became apparent that immunosuppression secondary to human immunodeficiency virus (HIV) may play an important role in its pathogenesis.

PATIENTS AND METHODS

Retrospective review of the records of 139 children with hemophilia followed up at our institution between January 1983 and January 1989 indicated that there were 4 cases of septic arthritis (2.9% incidence). Three of these patients presented during the past 2 years (January 1987 to January 1989). The

salient clinical and laboratory features of these 4 patients are summarized below and in Table 1.

Clinical Characteristics

The patients ranged in age from 7 months to 13 years. All had moderately severe or severe factor VIII deficiency (factor VIII level, <5 U/dL). Presenting features common to all four children included fever (temperature $>38^{\circ}\text{C}$) and persistent swelling and pain despite appropriate factor replacement for an apparent hemarthrosis. The duration of symptoms prior to admission ranged from 2 to 7 days. All patients received factor VIII concentrate during this period; the total number of infusions ranged from two to eight. On physical examination, only one patient was described as appearing ill. None of the children had other obvious sites of infection at the time of admission; however, three of them developed this complication in a joint previously affected by recurrent bleeding ("target" joint).

Laboratory Features

All four patients presented with anemia. In two of the four patients, the hemoglobin value was lower than the usual baseline level (Table 1). The white blood cell count ranged from $4.8 \times 10^9/\text{L}$ to $12 \times 10^9/\text{L}$, with only two patients displaying a marked left shift (band leukocyte count $>0.5 \times 10^9/\text{L}$) in the differential cell count. Platelet counts were normal or slightly elevated in all four children. An elevated erythrocyte sedimentation rate (81 to 135 mm/h by Westergren method) was documented in each patient. The joint fluid was described as purulent in one patient and serosanguineous in two. Cell count and Gram's stain of the joint fluid was obtained in only two patients. Both samples had increased numbers of white blood cells ($96.8 \times 10^6/\text{L}$ and $357 \times 10^6/\text{L}$); in one patient, bacteria were demonstrated by Gram's stain. All four patients had a positive blood culture, with the same organism isolated from the diseased joint: *Streptococcus pneumoniae* in two patients, *Staphylococcus aureus* in one patient, and β -lactamase-negative *Haemophilus influenzae* type B in the other. Three of the patients were HIV-antibody positive by both enzyme-linked immunosorbent assay and Western blot methods⁶; the fourth was

HIV-antibody negative. Two of the three seropositive patients had CD4 (helper) lymphocyte counts of $0.61 \times 10^9/\text{L}$ and $0.55 \times 10^9/\text{L}$ at the time of presentation with septic arthritis; the third developed infectious arthritis in 1983, when quantitation of CD4 cells was not routinely performed in our center. However, in 1987 this patient's CD4 cell count was within the normal range ($0.91 \times 10^9/\text{L}$).

Hospital Course and Outcome

Initial treatment in three patients consisted of factor VIII concentrate at doses of 30 to 50 U/kg every 12 hours (with a dose given immediately prior to joint aspiration), diagnostic aspiration of the affected joint, and initiation of intravenous antibiotics. The fourth patient (patient 2) had joint aspiration after 5 days of hospitalization, since septic arthritis was not suspected initially. Surgical drainage and débridement, followed by irrigation of the affected joint, was carried out in three patients. One of the children (patient 1) required a transfusion of 3 U of packed red blood cells due to severe blood loss through a drain placed in the affected joint.

The mean hospital stay was 16.5 days (range, 13 to 25 days). One patient (patient 3) was readmitted 1 week after discharge with acute onset of pain and swelling in the previously infected joint. Although he was afebrile, he was treated for 1 additional week with immobilization, factor VIII concentrate, and antibiotics. Three of the patients had chronic damage in the involved joint prior to the infection described herein, and their limited range of motion diminished further after the episode of septic arthritis.

COMMENT

Septic arthritis appears to be an increasingly common complication in patients with hemophilia. To the best of our knowledge, this current report constitutes the largest pediatric series from a single institution. Our four patients displayed clinical features that are very similar to those described previously (Table 2). It is clear from our experience and that of others^{8,7,8} that septic arthritis must be included in the

ifferential diagnosis of patients with hemophilia presenting with fever and a relatively prolonged (several days) history of localized joint pain and swelling refractory to appropriate doses of factor replacement. Suspicion of this entity should prompt the physician to aspirate the affected joint, and if the joint fluid is abnormal, initiate intravenous antibiotic therapy to limit the sizable morbidity associated with this complication.⁷

All of our patients presented with anemia, a finding previously described

in patients with hemophilia⁹; however, two of them had hemoglobin values that were lower than their usual measurements. In the absence of an obvious source of blood loss (eg, a large hemarthrosis), we speculated that the decline in hemoglobin in these two patients might have resulted from an acute episode of inflammation (ie, septic arthritis) that further depressed erythropoiesis.^{10,11} This phenomenon has been previously described in nonhemophiliacs with septic arthritis.¹⁰

Several authors^{3,4,12} have suggested that the localized joint infection in these patients results from a preceding episode of bacteremia. Our findings support this view, since the same organism was isolated from both the blood and joint fluid in all of our patients.

Although our numbers are small, several observations make us believe that HIV infection may have a pathophysiologic role in the development of septic arthritis in hemophilic patients. First, 3 of our 41 HIV-seropositive patients

have developed this complication (7% incidence). Second, it is well known that HIV infection causes multiple derangements in both T and B cell number and function,^{13,14} with affected individuals prone to develop serious bacterial infections due to *S pneumoniae*, *S aureus*, *Salmonella*, and *H influenzae*.¹⁴ Third, there has been a clustering of articles describing patients with hemophilia and septic arthritis between 1981 and 1985 (Table 2). Although the HIV serologic status of the patients is not mentioned in these previous reports, during this time period many patients with hemophilia receiving commercial factor concentrate were infected with HIV.¹⁵ Finally, a recent abstract and letter to the editor suggest that septic arthritis may be especially prevalent among HIV-infected hemophiliacs.^{16,17}

An interesting finding was the presence of pneumococcal arthritis in two of our HIV-seropositive patients and in three of the pediatric cases reported in the literature. This organism is an uncommon cause of infectious arthritis in nonhemophilic children older than 2 years of age.¹⁸ Although difficult to prove, the relatively high incidence of *S pneumoniae* septic arthritis in our patient population may be the result of altered immune function secondary to HIV infection.

One of our patients (patient 4) is unique in several respects. To our knowledge, he is the youngest hemophiliac described with septic arthritis and the only patient whose infecting organism was *H influenzae* type B. This association may be purely coincidental, since *H influenzae* type B is the most common cause of septic arthritis in chil-

dren less than 2 years of age.¹⁹ Yet, like the other cases reported herein, the insidious onset and failure to respond to appropriate doses of factor replacement suggested an initial episode of hemarthrosis.

In summary, within the past 6 years approximately 3% of the children with hemophilia attending our center have developed septic arthritis. We believe that all physicians caring for hemophiliacs should be aware that joint infections constitute a major disease complication. Diagnostic aspiration of an affected joint should be strongly considered in patients who have fever, persistent joint pain, and swelling despite appropriate doses of factor replacement. Based on our findings, HIV seropositive hemophilic children may be particularly susceptible to the development of septic arthritis. We encourage other centers that care for hemophilic children to review the incidence and pathophysiologic role of this complication.

This work was supported in part by Comprehensive Hemophilia Center grant MCJ-482003-05 from the Division of Maternal and Child Health, Department of Health and Human Services, Washington, DC.

Parent, Teacher, Child

A Trilateral Approach to Attention Deficit Disorder

Melvin L. Cohen, MD; Patrick C. Kelly, DO; A. W. Atkinson, MD, PhD

• We compared the effectiveness of three instruments in initially diagnosing and monitoring children with attention-deficit disorder with and without hyperactivity (ADD/H). Twenty-one children clinically assessed as having ADD/H and meeting criteria of the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition*, were examined initially and after treatment with methylphenidate hydrochloride and placebo. The following instruments were used: the ADD-H Comprehensive Teacher Rating Scale, the Connors' Parent Rating Scale-Revised, and the Gordon Diagnostic System. The ADD-H Comprehensive Teacher Rating Scale initially classified 67% of the children as having ADD/H and 14% as borderline. The Connors' Parent Rating Scale-Revised identified 71% as having ADD/H, while the Gordon Diagnostic System assessed 52% as having ADD/H and 29% as borderline. With methylphenidate treatment, the mean scores on the ADD-H Comprehensive Teacher Rating Scale displayed an increase in attention span and a decrease in hyperactivity, the Connors' Parent Rating Scale-Revised showed a significant decrease in ADD/H behavior, and the Gordon Diagnostic System mean scores indicated no significant change. (AJDC. 1989;143:1229-1233)

Accepted for publication April 27, 1989.

Many assessment instruments have been developed to aid in the diagnosis and treatment of children with attention deficit disorder with and without hyperactivity (ADD/H). Some are based on behavioral observations by parents or teachers, while others evaluate the child's performance of a given task. The *Diagnostic and Statistical Manual of Mental Disorders, Third Edition (DSM-III)*, established operational diagnostic criteria for ADD/H¹ that allow for a comparison of available clinical tools. The purpose of this study was to compare and contrast a parent observation-dependent, a teacher observation-dependent, and a child performance-dependent instrument in the diagnosis and methylphenidate hydrochloride treatment of children with ADD/H who satisfied *DSM-III* criteria.

SUBJECTS AND METHODS Instruments Used

Connors' Parent Rating Scale-Revised (CPRS-R).—Developed by C. Keith Connors, PhD, and frequently referred to as the Connors' Parent Questionnaire, the CPRS-R is probably the most commonly used parent rating scale for ADD/H.² This 48-item instrument contains major groupings in conduct problems, learning disability, psychosomatic problems, impulsivity-hyperactivity, and anxiety. Ten of the 48 items make up a separate hyperactivity index used to rate the subjects in this study, with each question being answered "not at all," "just a little," "pretty much," or "very much." The number of points assigned for each response is 0, 1, 2, or 3, respectively. The sum of responses is obtained, with a score of 15 or greater generally accepted as a cutoff for a determination of hyperactivity.²

ADD-H Comprehensive Teacher Rating Scale (ACTeRS).—The ACTeRS was designed to be useful to clinicians for the diagnosis and monitoring of treatment effects in

children with ADD/H.³ This scale includes 24 items describing classroom behavior on four factors: attention, hyperactivity, social skills, and oppositional behavior.⁴ The items are scored on a scale of 1 (almost never) to 5 (almost always). The raw score for each factor is transferred to a profile sheet displaying a percentile score for each of the four factors. Separate profiles have been developed for boys and girls. Teacher responses on the attention and hyperactivity factors were evaluated in this study. Scores on the attention or attention and hyperactivity subscales of less than or equal to the 10th percentile were considered diagnostic of ADD/H.

Gordon Diagnostic System (GDS).—The GDS involves a computerized portable device consisting of a box with a button and video display screen that allows administration of two child performance tasks (delay and vigilance).^{5,6} The delay task requires the child to inhibit pushing the button for a non-specified period (6 seconds) to score a point seen on the video screen. This task is a measure of impulse control, and the number of appropriately inhibited responses divided by the total number of responses gives an efficiency ratio. The vigilance task requires the child to press the button every time a sequence of numbers (ie, a 1 followed by a 9) appears on the screen. This is a continuous performance task that yields totals for correct responses and the number of errors of commission (extraneous pushes). Scores on these three subtests (efficiency ratio, correct responses, and errors of commission) are rated as normal, borderline, or abnormal on the basis of normative data by age.⁷

Subjects

This study was conducted by the developmental pediatric service of a military medical center that serves the needs of over 49 000 children of active-duty and retired military service members. Subjects meeting protocol criteria were enrolled as they arrived at this clinic on open referral from parents, schools, or physicians. All patients were examined and followed up by board-certified pediatricians who had completed or were currently

enrolled in developmental pediatric fellowships. The protocol was approved by the institutional review board, and informed consent was obtained from parents and children. Twenty-six subjects between the ages of 8 and 12 years clinically diagnosed as having ADD/H who also met *DSM-III* criteria for this disorder were studied, and none of them had been previously treated with stimulant medication. Five subjects were subsequently removed from the study, and the data on the remaining 21 were used for analysis. All children were of normal intelligence (IQ, ≥ 80 by standardized testing). Three (14%) of the 21 subjects were girls, learning disabilities had been diagnosed by the school in 33% (7/21) of the sample, and 9 (43%) had repeated a grade in school. Further descriptive variables of this group are presented in more detail elsewhere.⁸

Methods

Extensive developmental, educational, behavioral, and social histories were obtained, and thorough physical and neurodevelopmental evaluations were performed. Participants were demonstrated to conform to *DSM-III* criteria by inquiry of parents, teachers, or both by means of the symptoms listed in the *DSM-III*. The children were then placed randomly in methylphenidate-placebo or placebo-methylphenidate groups in a double-blind fashion. Medication was administered twice daily (in the morning and at noon) on school days only. A fixed dose of 5 mg twice daily for children weighing less than 30 kg and 10 mg twice daily for those weighing 30 kg or more was used. Total daily dose ranged from 0.3 to 0.6 mg/kg.

The ACTeRS, CPRS-R, and GDS scores were obtained initially, 1 month later at the time of crossover, and 1 month after this at the conclusion of the study. Separate prescriptions were given to the parents and the school, with written instructions for appropriate administration. The interval between the last dose of medication and the beginning of the GDS ranged from 1 to 4 hours, with the majority of tests being administered within 2 hours of dosing. Parents were asked at crossover and at the conclusion of the study to give their opinion on whether their child was receiving active medication or placebo.

The instruments were considered in agreement with *DSM-III* criteria for diagnosing ADD/H if the following criteria were met: (1) a score of greater than or equal to 15 on the CPRS-R hyperactivity index; (2) a score of less than or equal to the 10th percentile on the ACTeRS attention subscale or attention and hyperactivity subscales together; and (3) an abnormal rating on any of three GDS subtests (efficiency ratio, correct responses, and errors of commission). Borderline ratings for the ACTeRS were considered between the 10th and 20th percentiles on the attention subscale. The GDS was viewed as borderline if one or more subtests was borderline and no subtest was abnormal.

Two 8-year-old patients were unable to complete the vigilance portion of the GDS and were eliminated from the GDS portion of the methylphenidate and placebo trials; the GDS was not obtained on one patient during the active substance trial, and the ACTeRS was not completed on one patient receiving methylphenidate and three patients receiving placebo, thus explaining numerical discrepancies in the results.

Mean scores for the sample population were calculated for the ACTeRS attention and hyperactivity subscales, the CPRS-R hyperactivity index, and the GDS efficiency ratio, correct responses, and errors of commission subtests. In cases where more than one parent completed the CPRS-R or more than one teacher responded to the ACTeRS, the mean score of respondents was used for analysis. Data were analyzed by means of analysis of variance for repeated measures, taking into account the crossover feature of this study.

*ACTeRS indicates ADD-H Comprehensive Teacher Rating Scale; CPRS-R, Connors' Parent Rating Scale-Revised; GDS, Gordon Diagnostic System; A, abnormal; B, borderline; and N, normal.

†Subject was unable to perform task.

RESULTS

Agreement with *DSM-III* criteria was established in 71% by the CPRS-R, 67% by the ACTeRS, and 52% by the GDS. The Table lists the results for each of the participants, displaying a wide disparity in the ratings and demonstrating at least one abnormal result in 90% (19/21) of cases by one of the three tools. Of the two children rated as normal on all three instruments, both were abnormal on the ACTeRS hyperactivity subscale, and one was unable to complete the GDS vigilance subtest. Further analysis of the initial ACTeRS results revealed that the inclusion of borderline attention ratings raised the sensitivity of the instrument to 81% and also displayed a subsample of children rated as hyperactive only. The inclusion of borderline ratings on the GDS increased sensitivity to 81% against *DSM-III*. The initial results on the three instruments are displayed in Fig 1.

Fig 1.—Initial status of the three instruments vs the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition*, criteria for a diagnosis of attention-deficit disorder with (ADD/H) and without (ADD) hyperactivity. ACTeRS indicates ADD-H Comprehensive Teacher Rating Scale; CPRS-R, Connors' Parent Rating Scale-Revised; GDS, Gordon Diagnostic System; NL, normal; HYPER, hyperactive; and BORD, borderline.

Fig 2.—The Connors' Parent Rating Scale-Revised response status initially and after administration of methylphenidate hydrochloride or placebo.

Under the influence of methylphenidate, mean scores on the ACTeRS demonstrated a marked increase (improvement) in attention ($P < .002$) and a very marked decrease (improvement) in hyperactivity ($P < .001$). The CPRS-R displayed a significant decrease (im-

provement) in hyperactive behavior ($P < .005$). The GDS mean scores on efficiency ratio, correct responses, and errors of commission demonstrated no significant change under the influence of active substance. Individual instrument classification of the subjects as

normal, abnormal, or borderline (ACTeRS and GDS) for the three trials (initial, methylphenidate, and placebo) are graphically displayed in Figs 2 through 4. A placebo effect for the ACTeRS and CPRS-R was apparent but did not reach statistical significance. Parents accurately identified methylphenidate vs placebo at crossover and again at the conclusion of the study in 76% of cases.

COMMENT

This study compared the performance of three clinical tools in the diagnosis and follow-up of medication treatment of children with ADD/H. While the *DSM-III* criteria were used as the basis of comparison, each child underwent extensive evaluation, including review of parent and teacher reports, medical history, physical and neurodevelopmental examinations, and non-standardized clinical observations, before diagnosis. Clinicians examined the children for evidence of inattention, impulsivity, and hyperactivity unexplained by apparent physical, emotional, educational, or social circumstances.

Fig 3.—The Attention-Deficit Disorder With and Without Hyperactivity Comprehensive Teacher Rating Scale response status initially and after administration of methylphenidate hydrochloride or placebo.

Fig 4.—The Gordon Diagnostic System response status initially and after administration of methylphenidate hydrochloride or placebo.

In addition, a clinical determination of a need for stimulant medication intervention was made in each case. Both of the above were met before enrollment in the study, and all of the subjects selected in this fashion were subsequently demonstrated to meet *DSM-III* criteria for ADD/H. Alternatively stated, the *DSM-III* criteria were 100% sensitive when compared with a clinical diagnosis of ADD/H severe enough to warrant pharmacotherapy. While recognizing a

need for operational criteria for ADD/H, we maintain that meticulous clinical evaluation should remain the major determinant of the presence of signs and symptoms of this disorder, with the studied and other instruments offering important supportive data.

Since completion of this project, a revision of the *DSM-III* has occurred, resulting in an alteration of *DSM-III* criteria for ADD/H. We regret these changes because a clear separation of

attention-deficit disorder with and without hyperactivity is no longer available. The previous edition of the *DSM-III* divided symptoms into separate criteria of inattention, impulsivity, and hyperactivity.¹ Presence of a symptom complex including inattention and impulsivity with the absence of hyperactivity allowed a diagnosis of attention deficit disorder without hyperactivity.¹ The revised *DSM-III* lists 14 symptoms, with the presence of 8 of these required for a diagnosis of the now designated attention deficit hyperactivity disorder.^{9(pp50-52)} These 14 items are based on a national field trial of criteria for disruptive behavior disorders and are arranged in descending order of discriminatory power.^{9(pp50-52)} The revised manual does offer the undefined category of undifferentiated attention deficit disorder, which includes disturbances previously designated as attention deficit disorder without hyperactivity.^{9(p86)} Our results on the ACTeRS appear to support the previously published *DSM-III* diagnostic criteria in that we found 10% (2/21) of children to be abnormal on the attention subscale with normal ratings on hyperactivity and 29% (6/21) with abnormal attention and borderline hyperactivity.

The previous edition of the *DSM-III* advised, given conflicting reports between parents and teachers, that clinicians should give greater consideration to the observations of educational professionals due to their greater familiarity with age-appropriate norms.¹ The revised edition of *DSM-III*, while eliminating this problematic recommendation, offers no advice to the clinician faced with this dilemma. Therefore, a trilateral approach using a parent observation-dependent, a teacher observation-dependent, and a child performance-dependent instrument is attractive. However, in our study the result with the child performance instrument (GDS) was abnormal in only 50% (5/10) of cases of conflicting ratings between the parent- and teacher-dependent tools. While the inclusion of borderline ratings by the GDS would raise the sensitivity of this tool and increase interinstrument agreement, further research into the establishment of a more sensitive child performance tool seems worthwhile.

The cost of the three instruments is important; the ACTeRS and CPRS-R are inexpensive when compared with the purchase price of the GDS. This factor leads us to suggest that use of the GDS may at present be most appropriate in research or large-scale screenings.

The ACTeRS was responsive to methylphenidate effect, a finding consistent with those of previous published reports.^{10,11} A placebo effect, while not reaching statistical significance, could present interpretive difficulties as the mean scores for the ACTeRS (attention and hyperactivity) improved from abnormal to borderline under the use of placebo but were in the normal range after the methylphenidate trial. Ullmann and Sleator¹¹ demonstrated a subgroup of apparent placebo responders to the ACTeRS, which could explain this finding, but the size of our sample did not allow for subgrouping of the participants. The CPRS-R was also sensitive to active substance, demonstrating an increase of greater than 1 SD. Our finding of significant improvement in the CPRS-R due to methylphenidate effect differs from that of a recently published report¹² and is interesting in that, due to the experimental design, parents had minimal contact with their children during previously suggested¹³ peak behavioral effects of the medication. We believe that this represents either a carryover effect of the medication or the influence of teacher observations on parental responses. While previous publications^{12,14} have suggested the possibility of a decline in scores on the first and second administrations of the CPRS-R,

we found no order effect on the instrument. The GDS did not demonstrate improvement under the influence of active medication. Barkley et al¹² demonstrated no effect of methylphenidate on the GDS delay or vigilance tasks when using low-dose medication. They did, however, find a statistically significant improvement in child performance on the GDS vigilance subtests when employing doses higher than those in our study. The lack of a uniform time between medication dosage and GDS administration is potentially problematic; however, the range of 1 to 4 hours is within previously determined behavioral effects of methylphenidate.¹³

While our study addressed the sensitivity of the CPRS-R, GDS, and ACTeRS vs the *DSM-III* criteria for ADD/H, it did not offer information regarding specificity of the tools, and this remains an important area of future research.

CONCLUSIONS

We conclude that the CPRS-R, ACTeRS, and GDS demonstrate utility in the diagnosis of children with ADD/H, but clinicians should avoid overreliance on any one of the individual instruments. Borderline ratings on the ACTeRS and GDS should be given clinical consideration as supportive of a diagnosis of ADD/H. The ACTeRS and CPRS-R appear helpful in monitoring the effects of treatment with methylphenidate, while the GDS does not appear sensitive to the effects of this substance at the dosages used in this study. We further offer a trilateral procedure using a parent observation, a teacher

observation, and a child performance instrument as an extremely sensible clinical approach that deserves consideration. Ideally, such a procedure would employ instruments with utility in both the diagnosis and follow-up of medication treatment of the children. As the GDS was not sensitive to the effects of methylphenidate, we cannot suggest this instrument as the child performance arm of such an approach.

While our study addressed the utility of the three instruments in the approach to children with ADD/H, it is not our intent to suggest medication as the sole variable involved in a positive outcome for those with this disorder. In our view, children with ADD/H require a multimodal approach employing selected elements of behavioral modification, family therapy, and educational adjustments in addition to indicated pharmacologic adjuncts.⁸

Despite ongoing development, revision, and refinement of instruments to assist in the diagnosis and treatment of children with ADD/H, we presently view meticulous clinical assessment and follow-up tailored to individual children as the most important factor in an appropriate approach to this multifaceted problem. The three studied clinical tools provide varying degrees of supportive data during assessment and treatment of children with ADD/H.

We thank Ciba-Geigy Pharmaceuticals, Summit, NJ, for providing the placebos. We also thank Michael R. Weir, MD, and Dan C. Moore, MD, for their review of the manuscript and Sue Lamonde and Martha San Nicolas for their editorial support and assistance with manuscript preparation.

School Breakfast Program and School Performance

Alan F. Meyers, MD, MPH; Amy E. Sampson, PhD; Michael Weitzman, MD; Beatrice L. Rogers, PhD; Herb Kayne, PhD

• To test the hypothesis that participation in the School Breakfast Program by low-income children is associated with improvements in standardized achievement test scores and in rates of absence and tardiness, children in grades 3 through 6 were studied in the Lawrence, Mass, public schools, where the School Breakfast Program was begun at the start of the second semester 1986-1987 school year. The changes in scores on a standardized achievement test and in rates of absence and tardiness before and after the implementation of the School Breakfast Program for children participating in the program were compared with those of children who also qualified but did not participate. Controlling for other factors, participation in the School Breakfast Program contributed positively to the 1987 Comprehensive Tests of Basic Skills battery total scale score and negatively to 1987 tardiness and absence rates. These findings suggest that participation in the School Breakfast Program is associated with significant improvements in academic functioning among low-income elementary school children.

(AJDC. 1989;143:1234-1239)

Disparities in educational achievement between poor and nonpoor children have long been recognized and have been the cause of grave social concern. Attempts to compensate for these disparities have resulted in large-scale social and educational efforts, such as the Head Start program, Title I com-

pensatory education, and early intervention. Nutritional problems that are more common among poor children, such as failure to thrive and iron-deficiency anemia, have been linked to academic problems.^{1,2} To date, however, there has been limited evidence supporting the role of school nutrition programs in improving the academic performance of children raised in poverty.

The School Breakfast Program (SBP) was created by Congress in 1966 (Public Law 89-642) for the primary purpose of offering a morning meal to low-income children who would otherwise have none.³ The SBP is administered nationally by the Food and Nutrition Service of the US Department of Agriculture, Washington, DC, and locally by participating school boards. Both the SBP and the National School Lunch Program offer meals to students at full price, reduced price, or free, according to uniform national eligibility criteria based on family income and size. The current Department of Agriculture criterion for eligibility for free meals is family income of 130% or less of poverty level income, and for reduced-price meals, family income of 130% to 185% of poverty level income.⁴

National survey data from 1980 show that the lunch program was available to 96% of public school children in the United States, while the breakfast program was available to only 39% of children.^{4,5} In 1986, the SBP served an average of 3.3 million meals each school day at an annual cost to the federal government of \$406 million; 84% of these meals were provided free and 4% were provided at a reduced price.⁶

Data from the National Evaluation of School Nutrition Programs (NESNP) show that the 24-hour dietary intake of children participating in the SBP is superior to that of nonparticipants who eat no alternative breakfast.⁵ It is possible that there may be other benefits associ-

ated with participation in the SBP by low-income children, such as an improvement in academic function. Such an effect is suggested by the studies of Pollitt and colleagues^{7,8} that demonstrated improved performance on morning tests of cognition by 9- to 11-year-old children following breakfast compared with their performance in the fasting state. To date, little published literature has examined the effects on academic performance of the SBP as currently administered.⁹

In August 1986, the Commonwealth of Massachusetts enacted legislation (Chapter 346, Acts of 1986) mandating the implementation of the SBP in those schools not offering the program and in which 40% or more of the school lunches were served for free or at reduced price ("severe need" schools). This circumstance enabled us to study the academic effects associated with participation in the breakfast program in a "natural experiment," in which all children in a large school district were offered the breakfast program in 1987 for the first time.

METHODS

Hypotheses

The hypotheses tested in this study were the following: (1) Low-income children who participated in the SBP for the first time would improve their academic performance, as measured by scores on standardized achievement tests, compared with their own performance when no breakfast program was available, and this improvement would be greater than any improvement shown by similar low-income children who did not participate. (2) The SBP participants would show decreased rates of absence and tardiness compared with eligible nonparticipants.

Study Site

Of the five large school districts in eastern Massachusetts implementing the SBP under the new state legislation, Lawrence was the only school system in which standardized achievement tests were administered annu-

ally to all elementary grades and in which the superintendent and elementary school principals enthusiastically supported our study. Lawrence is an ethnically diverse city with a population of 63 175, of which 81% are white, 16% are Hispanic, and 2% are black. Nineteen percent of the general population and 31% of the child population live below the federal poverty level.¹⁰

In 1986, in the Lawrence Public School System, 71% of the children were low income, and thus eligible for free or reduced-price school meals. Sixty-three percent of these children were members of a minority group (58% Hispanic, 37% white non-Hispanic, 2% black, and 2% Asian); 40% of the families of these school children received Aid to Families With Dependent Children benefits (unpublished data from the Lawrence Public School System, 1986). The Comprehensive Tests of Basic Skills (CTBS), a widely used battery of standardized achievement tests, are administered annually in late April or early May to all grades, beginning in the second grade; the tests are given in the morning. The SBP was implemented in Lawrence in late January 1987, just prior to the start of the second semester of school year 1986-1987. Thus, the 1987 CTBS was administered after the SBP had been in place for 3 months.

Study Population and Data Collection

Six of Lawrence's 16 elementary schools were chosen to participate in the study. Schools were excluded from the study if they were not operating as elementary schools in 1985-1986, or if they contained two or fewer classrooms in the study grades 3 through 6. All children in grades 3 through 6 in the study schools were considered eligible for the study if (1) they qualified to receive free or reduced-price school meals; (2) they were registered in the Lawrence public schools for the second semester of both school years 1985-1986 and 1986-1987; and (3) they were not retained during the study years. Parental consent forms were sent home with all the children in the study classrooms, and those children whose parent(s) indicated on the returned forms that they declined consent were not included in the study.

To classify a child as a SBP participant or nonparticipant, attendance at the school breakfast was monitored for 1 week. Breakfast program participation was recorded on site by school personnel during the week of May 4 through 8, 1987, for which they received monetary compensation. This was the week the CTBS was administered, over the course of 3 days. Children were considered for the study only if they had been present and not tardy on 3 or more days during the sample week, according to school attendance records. They were considered SBP partici-

Study design.

pants if they attended the school breakfast on at least 60% of these days, and considered nonparticipants if they did not attend the SBP on any of these days. The remaining children were excluded from the analysis.

Demographic data were obtained from student and school registration records. Grade and age were not both included as variables, since they are so closely related; we therefore chose to include only the student's grade, which we judged to be more accurately recorded. The CTBS scores for 1986 and 1987 (scale score for battery total and language, reading, and mathematics subtests) were obtained from a printed record supplied by the CTBS scoring company, contained in the students' records. To compare the children's absence and tardiness rates before and after the implementation of the SBP, attendance and tardiness data for the spring semesters of 1986 and 1987 were collected from the central data registry of the Lawrence public schools. The study was approved by the Human Studies Committee of the Trustees of Health and Hospitals of the city of Boston.

Study Design and Statistical Methods

For each child, changes in CTBS scores were calculated by subtracting the scale scores for 1986 (prior to the SBP implementation) from the corresponding 1987 score

(after the SBP was in place). Since the SBP was implemented at the start of the second semester of school year 1986-1987, rates of absence and tardiness were compared for the second semesters of school years 1985-1986 and 1986-1987 (Figure). Absence and tardiness rates were calculated for each student by dividing the number of days the child was absent or tardy by the number of days the student was registered for school, and expressed as a percentage. Changes in absence and tardiness rates were calculated by subtracting the rate for the second semester 1985-1986 from the rate for the second semester 1986-1987.

If a child was absent or tardy for more than one fourth of either study semester, or was registered for fewer than half the total school days in session for either semester, the child was excluded from the analyses of absence and tardiness rates. One-way analysis of variance (ANOVA) was used to determine if the changes in CTBS scores, absence rates, and tardiness rates were significantly different for participants in the SBP compared with eligible nonparticipants. The ANOVA was used rather than the more familiar Student's *t* test to test for interaction effects. These two groups were also compared with regard to their 1986 (pre-SBP) CTBS scores, attendance, and tardiness using one-way ANOVA. The demographic characteristics of SBP participants and nonparticipants were compared using the χ^2 statistic.

*Participants are defined as those children who were present and on time 3 or more days during the sample week, and who attended SBP at least 60% of the days they were present. Nonparticipants are defined as those children who were present and on time 3 or more days and who did not attend SBP on any days they were present. Sixty-nine children were absent more than 2 days during the sample week and were excluded from the analysis.

Multiple regression analysis was used to determine the contribution of independent variables, including demographic characteristics, income category, SBP participation status, and 1986 CTBS scale scores and second semester absence rates to the dependent variables. These dependent variables, or outcome measures, were defined as each child's 1987 CTBS scale scores for battery total and for subtests in language, reading, and mathematics and each child's 1987 absence and tardiness rates.

RESULTS

Study Sample and Participation

There were 1954 children in grades 3 through 6 in the study schools. Of these children, 1573 (80.5%) qualified for free or reduced-price meals. The parents of 119 (7.6%) of these children declined participation in the study. Of the 1454 children remaining, 1171 were in the Lawrence schools during both study semesters, and school records were avail-

able for a total of 1092 children. Of these children, 1023 were SBP participants or nonparticipants by our study definition; 69 children (6.3%) did not meet the definition for participant or nonparticipant and were excluded from the study sample. Three hundred thirty-five children from the study sample of 1023 (33%) were SBP participants.

Demographics of Participants and Nonparticipants

Demographic characteristics of the study sample are shown in Table 1. Participants in the SBP did not differ significantly from nonparticipants with regard to sex, number of children in the family, language spoken at home, or ethnicity. Participants were significantly more likely than nonparticipants to be in grades 3 or 4 vs grades 5 or 6, to be in transitional bilingual classes vs English-only classes, and to qualify for free

meals as opposed to reduced-price meals. For 94% of the children in the sample, the language spoken at home was either Spanish or English, and 93% of the children in the sample were either Hispanic or non-Hispanic whites.

Performance Changes for SBP Participants and Nonparticipants

Table 2 shows the mean CTBS battery total scale scores, subtest scale scores for language, reading, and mathematics, and attendance and tardiness rates for program participants and nonparticipants for 1986 (pre-SBP) and 1987 (post-SBP), and the mean change in these values. Program participants had significantly lower scores than nonparticipants in 1986 for CTBS battery total ($P < .01$), reading ($P < .05$), and mathematics ($P < .01$), and marginally lower scores for language ($P < .1$). Absence and tardiness rates for the second semester 1985-1986 (pre-SBP) did not differ between the two groups. Increases in scores from 1986 to 1987 were significantly greater for the SBP participants than nonparticipants in CTBS battery total scale score ($P < .01$), language subscore ($P < .05$), and marginally greater for mathematics ($P < .1$) and reading ($P < .1$). Tardiness rates decreased for participants and increased for nonparticipants ($P < .01$).

Independent Effect of SBP Participation on Performance

Only the children who were either Hispanic or white non-Hispanic (93% of the study sample) were included in the multiple regression analysis. Due to the high degree of collinearity (that exists when two variables vary together so closely that their independent effects cannot be distinguished) between ethnicity and language spoken at home ($r = .8$) and to the fact that virtually all the students in transitional bilingual education classes were Hispanic, only ethnicity was included in the regression model. This analysis employs casewise deletion, and thus any case with missing data for any independent variable was excluded from the analysis. Regression results are presented in Table 3.

Each coefficient represents the difference in the dependent variable that can be expected as a result of a unit change in the independent variable be-

Table 2.—Mean Test Scores and Absence and Tardiness Rates of School Breakfast Program (SBP) Participants vs Nonparticipants Before and After SBP Implementation*

Dependent Variables	1986 (Pre-SBP)			1987 (Post-SBP)			Change From 1986 to 1987

*See Table 1 for definition of participation.

†CTBS indicates Comprehensive Tests of Basic Skills.

ng examined. Thus, the increment of 5.44 represents the expected increase in the CTBS battery total score that is associated with school breakfast participation, all other variables being held constant. School Breakfast Program participation contributed significantly to the prediction of 1987 CTBS battery total scale score ($P < .05$), and followed only grade in school and 1986 battery total scale score in the weight of its contribution. Participation contributed negatively to 1987 rates of absenteeism ($P = .05$) and tardiness ($P = .0001$).

COMMENT

In this study of the effects of SBP on school performance, we found that participation in the program by low-income children had a significant association with improvement in standardized achievement test scores and rates of absence and tardiness. Several previous controlled experimental studies, conducted in a classroom setting, suggested that there may be academic benefits associated with morning feedings¹¹⁻¹⁴; others have found no effect.¹⁵ Two experimental breakfast programs have been reported. In one, no academic benefits were found in the experimental school,¹⁶ and in the other, improvements in growth, hematocrit values, and attendance were found among children in the experimental school.¹⁷ Several non-experimental studies of the academic effects of school feeding programs have been reported as well; some have found improved academic performance,¹⁸ be-

*The effect of each independent variable is measured by the unstandardized coefficient of the variable in the multiple regression analysis. Each coefficient represents the actual change in score that could be expected from a unit change in the independent variable. Because these coefficients are related to the units of measurement, their relative magnitude cannot be directly compared. Dichotomous variables were coded as follows: SBP participation; 0 = nonparticipation, 1 = participation; income category; 0 = free meals, 1 = reduced-price meals; ethnicity; 0 = Hispanic, 1 = white non-Hispanic; sex; 0 = m, 1 = f.

†See Table 1 for definition of participation.

¶.001 $P \leq .01$.

$P \leq .001$.

havior,¹⁹ or attendance²⁰; one reported no effect on attendance.¹⁹ There have also been many anecdotal reports of improvements in school performance, tardiness, and attendance associated with the implementation of the SBP.^{6,20-24}

The academic improvements demon-

strated in this study could be due to either the immediate effects of a morning meal eaten at the start of the school day, a more long-term benefit related to improved 24-hour dietary intake, or a combination of both. If the improvement is related to the long-term effect of

improvements in dietary status, there may be even greater measurable effects for periods longer than the 3 months the program was in place in Lawrence prior to the 1987 achievement testing and the 5 months during which absence and tardiness were monitored. Recently, Benton and Roberts²⁵ showed that a vitamin-mineral supplement administered daily in school for a period of 9 months resulted in a statistically significant improvement in nonverbal intelligence test scores in a double-blind placebo-controlled trial among 12- and 13-year-old children in Britain.

The observed effect of SBP participation on achievement test scores in this study is seemingly modest. However, the national norms for the CTBS battery total scale score have an SD ranging from 41 to 50 in grades 3 through 6 (mean scale score increases each year between 12 and 43 points).²⁶ Thus, in our study, the increase in scores associated with breakfast program participation is in the range of 0.10 SD; by comparison, it is estimated that the Title I/Chapter 1 Compensatory Education Program narrowed the gap in achievement test scores between minority and nonminority students by 0.02 to 0.06 SD.²⁷ In those school districts using fixed cut points in standardized achievement test scores as criteria for promotion, score differences of this magnitude may mean the difference between promotion and retention.^{28,29}

Participation rates in the SBP in Lawrence were comparable with those found in the NESNP in 1980,⁴ in which participation rates were similarly estimated using a 5-day sample.³⁰ As in Lawrence, NESNP data showed that students tend to eat school breakfast either every day or not at all. Of those children approved for free or reduced-price meals in the NESNP sample, 21% received school breakfast on a typical school day where the program was available, compared with 33% in the Lawrence sample. In the NESNP sample, as in Lawrence, SBP participation decreased with increasing family income and increasing grade in school.

There are a number of limitations that must be taken into account in interpreting the findings of this study. This was not a controlled experiment, and thus causal inferences must be made with

caution. Since the children's participation status was determined by self-selection, it was not possible to control for some potentially confounding factors, such as motivation. The only data we were able to examine to characterize the two self-selected cohorts of breakfast program participants and nonparticipants were those available from school records and registration data.

Several variables that might be potentially confounding were therefore not examined, including family income within the broader categories of eligibility for free or reduced-price meals, educational attainment of the parents, single-parent family structure, or length of residence in the United States. In addition, we examined the grade and not the age of the children; therefore, it is possible that the age of SBP participants and nonparticipants may have differed. However, by excluding children who were retained during the study years, this possibility was reduced. While SBP participants and nonparticipants did not differ in many of the demographic characteristics studied, participants had significantly lower mean CTBS test scores in 1986 (pre-SBP).

While it is true that applying statistical tests of significance to multiple variables increases the probability of type I (false-positive) errors, it seemed useful to examine CTBS subscores as well as battery total scores and absence and tardiness rates. The consistency of the positive findings in multivariate analysis, and their agreement with the ANOVA results, suggests that while small in absolute magnitude, these are robust effects.

In examining the effect of SBP participation on CTBS scores, attendance, and tardiness, we were able to control for sex, ethnicity, grade, number of children in the family, income category, pre-SBP CTBS scores, absence rates, and tardiness rates, and still found an independent contribution of breakfast program participation to improvements in achievement test scores, absence, and tardiness. Since the 1986 CTBS scores were included as an independent variable in multiple regression analyses when determining the effect of SBP participation on 1987 scores and rates, regression to the mean could not explain the greater improvement of SBP partic-

ipants in their CTBS scores and absence and tardiness rates from 1986 to 1987. While additional data may explain a greater proportion of the variance in the outcome measures, there is no reason to suspect that a more comprehensive analysis would reveal diminished beneficial effects of SBP participation.

The findings reported here demonstrate improvements in academic performance, absenteeism, and tardiness associated with SBP participation among high-risk elementary school children living in poverty or near poverty. Further study of this important question is warranted, preferably using prospective controlled designs, and if such studies confirm these findings, it would appear that prudent public policy intended to address the educational disparity between poor and nonpoor children should include efforts to assure access to SBP for all low-income children. As advocates for the welfare of children, pediatricians should be aware of these potential benefits of the SBP for low-income children in their communities.

This study was supported by grant 87115587 from the William T. Grant Foundation, New York, NY, and by the Helmut Wolfgang Schumann Foundation, Hanover, NH.

We are grateful to the many people who helped us in the various stages of this study, including Eugene Thayer, Maureen Savastano, and James Scully, of the Lawrence public schools; Stanley Gershoff, dean of the Tufts University School of Nutrition, Medford, Mass; Tom Mela of the (Boston) Massachusetts Advocacy Center; George Madaus and colleagues of the Boston College Center for the Study of Testing, Evaluation and Educational Policy, Chestnut Hill, Mass; Helmut Schumann; Deborah Klein Walker, David Bellinger, and Jay Hirschman for their helpful comments; and the principals, teachers, parents, and students of the Lawrence public school system.

Book Review

The Diagnostic Approach to Common Symptoms and Signs in Infants, Children and Adolescents, by P. S. Bellet, 502 pp with illus, \$38.50, Philadelphia, Pa, Lea & Febiger, 1989.

In this book "for medical students and physicians involved in the care of infants, children, and adolescents," Dr Bellet describes his diagnostic approach to the common signs and symptoms confronting the practitioner. His approach is logical and the format is consistent. Seventy-six signs and symptoms were selected and make up the individual chapters. Each chapter begins with a definition of the condition, which is followed by the diagnostic possibilities. Each differential diagnosis is then briefly discussed and, finally, an outline of a diagnostic approach is offered. Each chapter concludes with a bibliography.

The major strength of this book is that it is a good resource in pediatric differential diagnosis for the nonseasoned clinician. It is not meant to be a single reference source or a comprehensive text. The book is singled authored, but still is somewhat uneven in that some chapters are stronger than others. I didn't find any major omissions of either common problems or their differential diagnoses, but discussions of some of the diagnostic possibilities were rather terse.

As with any book of limited scope, one can question the emphasis of the presentation. Discussion of some chapters is divided into acute and chronic conditions, whereas other discussions are limited to acute causes.

Another question that may be raised concerns the balance of material in the book. More than 5 pages are devoted to causes of acute abdominal pain, but recurrent abdominal pain is presented in less than one page. Some chapters are very short and others are much longer (ranging from slightly more than 1 page to 18 pages). I would have defined certain clinical conditions in slightly different ways than Dr Bellet does and at times cited slightly different statistics. Quibbling aside, there were only a few statements in the book that I took issue with (eg, that a dull gray or bright red tympanic membrane is sufficient to diagnose acute otitis media).

Superficiality is the major problem with this book. However, this is only a potential liability because on many occasions the clinician would refer to this book only to provide a quick review and to make sure that all diagnostic possibilities were considered. At other times, the reader will be disappointed that the book does not go into greater depth. Although the list of diagnostic problems is adequate, the "pearls" to hone in on in the diagnoses are often excellent, and the vast majority of statements are correct, the discussions are often too abbreviated. It is also doubtful that the experienced pediatrician would find each chapter's diagnostic approach section very useful because they are quite basic and general.

How does this book compare with other books on pediatric differential diagnosis? As with the others, it has its strengths and weaknesses. By suggesting what to do after the enumeration of possibilities, it tries to go beyond simply presenting differential diagnoses of common pediatric problems and, to a degree, it succeeds. This book contains more cross-referencing than the other books with which I compared it. The advantage of this design is that it enables greater integration of the material, but the disadvantage is that it forces the reader to do more page flipping, which can be somewhat distracting. Overall, *The Diagnostic Approach* compares favorably with others, although I don't believe it is superior to them. Clinicians will find it useful. Medical students, residents, and midlevel clinicians will find it the most useful, especially if used in conjunction with a more comprehensive text.

Professional Opportunities

FLORIDA — Seeking board-certified/board-eligible pediatrician to join busy solo pediatric practice on sunny west coast of Florida. Salaried position for one year leading to partnership. Please contact: D. French, MD, 1305-F South Fort Harrison, Clearwater, FL 34616. (813) 446-1161.

BOARD-CERTIFIED/-ELIGIBLE PEDIATRICIAN to join our 25-physician, multi-specialty group practice. All practice costs paid, full range of benefits and early partnership status. Experience our family-oriented community with its unsurpassed scenic beauty and outdoor recreational opportunities, situated midpoint between metropolitan Seattle and Vancouver, British Columbia. Contact: Shane Spray, 1400 East Kincaid Street, Mount Vernon, WA 98273. (206) 428-2524.

MASSACHUSETTS — Pediatrician, BC/BE, needed to join two others in busy private practice one hour west of Boston. Good coverage, hospital and salary. Mail CV to: Felix Perriello, MD, 114 Water Street, Milford, MA 01757. (508) 473-0231.

CALIFORNIA — PEDIATRIC INTENSIVIST to join progressive 13-bed PICU at Huntington Memorial Hospital in Pasadena, California, a major affiliate of the University of Southern California. Excellent salary, bonus and partnership opportunities. Persons with pulmonary training are encouraged to inquire. Inquiries to: Edgardo L. Arcinue, MD, Director, PICU, Huntington Memorial Hospital, 100 Congress Street, Pasadena, CA 91105. (818) 397-8688.

PEDIATRICIAN: BEMIDJI CLINIC MERITCARE is seeking a second BC/BE pediatrician to join an expanding 25-physician multi-specialty group. The local Level II hospital has 800+ deliveries per year and is affiliated with a tertiary care center with a NACHRI designated children's hospital. The area offers a wide range of recreational opportunities. Guaranteed first year salary with rewarding long term compensatory arrangements. Respond to: Robert C. Montgomery, MD, Physician Recruitment Chairman, Fargo Clinic MeritCare, 737 Broadway, Fargo, ND 58102. (800) 437-4010.

LINCOLN, NEBRASKA — BC/BE pediatrician to join three other pediatricians in a busy multi-specialty group. Available immediately, take over existing practice of retiring doctor. City of 150,000 has good schools and safe family environment. Good opportunity for professional growth. Competitive salary and benefits. Send CV to: R.Z. Gallion, P.O. Box 81009, Lincoln, NE 68501.

THREE PEDIATRICIANS SEEKING FOURTH for growing practice in 61-physician multi-specialty group in city of 10,000, 40 miles south of Madison. Attractive salary and benefits. Contact: James Raettig, MD, The Monroe Clinic, Monroe, WI 53566. (608) 328-7214.

PEDIATRICIAN will be welcomed to Oswego, New York, a 60,000 population primary service area. A college town located on Lake Ontario, 40 miles north of Syracuse. Exceptional educational, cultural and recreational activities, including salmon fishing. Contact: Garo Taft, MD, 110 West Sixth Street, Oswego, NY 13126. (315) 349-5526.

MOUNTAIN STATES COMMUNITIES need pediatricians. Smaller communities with excellent incentive packages and referral bases. All close to mountain recreation. Call Rita Longino at (505) 262-1871; or send CV to: Excel of Albuquerque, 1717 Louisiana NE, Suite 218, Albuquerque, NM 87110.

Professional Opportunities

PEDIATRICIAN — Southeastern Oklahoma, 90 miles to Dallas, near beautiful Lake Texoma. Modern general acute care, 100-bed facility, opened in 1987. One other pediatrician and two OB/GYNs in this community of 14,000. This opportunity is available in a university town, offering cultural and sporting events as well as an excellent school system. Reply to: Tom Rozewicz, Medical Center of Southeastern Oklahoma, 1800 University Drive, Durant, OK 74701. (405) 924-3080.

PEDIATRICIAN — Excellent opportunity for very successful practice with unlimited potential. Progressive community of 15,000 (referral area 70,000). Supportive medical staff will provide referrals and coverage, income guarantee plus incentives. Rick Addis, Director of Development, Van Wert County Hospital, 1250 South Washington Street, Van Wert, OH 45891. (419) 238-2390, or home (419) 238-9739.

TEXAS — PEDIATRICIAN. A pediatrician is needed to establish practice in conjunction with the recruitment of a neonatologist, in College Station, Texas, the home of Texas A & M University. Financial assistance with possible future group association. Send your CV to: Professional Relations, Department ADC-9C, P.O. Box 1438, Louisville, KY 40201-1438.

The Doctor Is In...

...private practice in the perfect community.

If that's your goal, Humana can help. We have over 80 hospitals in 20 states. Chances are we know of a private practice opportunity in the location of your choice. Consider these communities:

- Russellville, Alabama
- Anchorage, Alaska
- Los Angeles County, California
- Florida East Coast
- Atlanta, Georgia
- Lexington, Kentucky
- Louisville, Kentucky
- Somerset, Kentucky
- Chattanooga, Tennessee
- Lebanon, Tennessee
- Abilene, Texas
- College Station, Texas
- Layton, Utah
- (Salt Lake City/Ogden)

We have other Pediatric opportunities not listed here.

For further information, call TOLL-FREE 1-800-626-1590, or send your curriculum vitae to: Manager, Professional Relations, Humana Inc., Dept. ADC-9, 500 West Main Street, Louisville, KY 40201-1438.

Humana

Professional Opportunities

SOUTHERN CALIFORNIA—PEDIATRICIAN. A board-certified pediatrician, practicing in the San Fernando Valley for the past 10 years, is now seeking an associate. This is one of the busiest practices in the area. For further information send CV to: Manager, Professional Relations, Department ADC-9B, P.O. Box 1438, Louisville, KY 40201-1438. Or call toll-free: (800) 626-1590.

THE DEPARTMENT OF PEDIATRICS at William Beaumont Hospital is seeking a qualified pediatrician for the position of Director, Division of Pediatric Infectious Disease. William Beaumont Hospital is a 934-bed general hospital located thirteen miles north of Detroit in Royal Oak, Michigan. We have 30 general pediatric beds, a 30-bed NICU and 3,000 deliveries annually. Our department has a staff of 120 pediatricians and 20 full-time pediatric subspecialists. There are some 4,000 admissions annually to our general pediatric floor and 20,000 pediatric visits to the emergency center and outpatient clinics. We are a teaching hospital with independent residency programs in pediatrics and medicine-pediatrics, affiliated with the University of Michigan and Wayne State University. Interested candidates should call or submit their curriculum vitae to: M. Jeffrey Maisels, MD, Chairman, Department of Pediatrics, William Beaumont Hospital, 3601 West Thirteen Mile Road, Royal Oak, MI 48072. (313) 551-0412.

WESTERN STATES — BE/BC pediatricians for multi-specialty clinics, hospitals. Also, private California practices for sale. Call/send CV: Bradshaw Associates, 21 Altamont, Orinda, CA 94563. (415) 376-0762.

MASSACHUSETTS — Two BC pediatricians seeking one or two BC/BE pediatricians. Southeastern Massachusetts coastal community. Easy access to Boston and Providence. Rapidly growing practice and good hospital, recreation, spouse job opportunities, schools. Send CV: Dr. J. Conway and Dr. S. Rogers, 53 Marion Road, Wareham, MA 02571.

PEDIATRICIAN — BIRMINGHAM, ALABAMA. BC/BE pediatrician needed to join busy three person practice with base office and satellites. Located less than one mile from large tertiary medical center with pediatric unit and neonatal intensive care unit, staffed with dedicated and qualified pediatric and neonatal intensive care nurses. Birmingham, recently named as one of our country's most livable cities, offers excellent climate, as well as progressive industry, education and recreation. Position will initially be salaried with partnership option after two years. Interview and relocation expenses offered. Interested individuals should send CV to: Kay Channell, Assistant Vice President, Baptist Medical Center Montclair, 800 Montclair Road, Birmingham, AL 5213.

UTAH — PEDIATRICIAN. An extremely busy and well-established pediatrician in Layton, Utah is now seeking an associate. This physician has two offices, one of which is located next to our 110-bed hospital. Layton, located just 20 miles north of Salt Lake City and 15 miles south of Ogden, has a service area of 140,000, 70% of whom are under the age of 35 with large families. For further information, send your CV to: Manager, Professional Relations, Humana Inc., Department ADC-9A, 500 West Main Street, Louisville, KY 40201-1438. Or call toll-free: (800) 626-1590.

NEW YORK, NEONATOLOGIST — Department of Pediatrics, State University of New York at Buffalo/Children's Hospital is seeking faculty member to join eight-member division of neonatology. Assistant or associate professor level. BC in pediatrics, IC/BE in neonatology. Division conducts NIH-sponsored laboratory research on perinatal pulmonary and circulatory physiology and clinical research in pulmonary physiology, immunology and gastroenterology, including five years experience with surfactant therapy. CV to: Frederick C. Ionn, MD, Chief, Division of Neonatology, Children's Hospital, 219 Bryant Street, Buffalo, NY 4222. Affirmative action/equal opportunity employers.

C/BE PEDIATRICIAN needed immediately to join our member pediatric department of 100-member, multi-specialty clinic with 26 satellite locations. Metropolitan population of approximately 150,000 and university affiliation. Contact: T. Mausbach, MD, akota Clinic, Ltd., P.O. Box 6001, Fargo, ND 58108. (701) 280-3346.

COLORADO — BC/BE pediatrician to join well-established, two-person practice. Active Level II nursery. Reply to: Richard Booth, MD, 1148 East Elizabeth, Fort Collins, CO 80524. (303) 484-4871.

NEONATOLOGIST — The Department of Pediatrics, William Beaumont Hospital is seeking a fifth full-time, academically-oriented neonatologist to join our Division of Newborn Medicine. The position involves clinical care, teaching and research. We are interested in recruiting somebody with demonstrated capability and interest in clinical and/or basic research, as well as proficiency in teaching residents. Interested individuals should submit their CV to: Daniel Batton, MD, Chief, Division of Newborn Medicine; or M. Jeffrey Maisels, D, Chairman, Department of Pediatrics, William Beaumont Hospital, 3601 West Thirteen Mile Road, Royal Oak, MI 48072.

Chair, Department of Pediatrics

The Allentown Hospital — Lehigh Valley Hospital Center, an 823-bed tertiary care teaching hospital in eastern Pennsylvania, is seeking a board certified pediatrician to become the first full-time Chair of its Department of Pediatrics. The successful candidate will be an accomplished clinician with the enthusiasm and vision to build a progressive, well-organized department. We will look to the Chair to create programs to assist us in providing better inpatient services, to recruit subspecialists appropriate to a service area of close to ¾ of a million people and to encourage links with educational institutions aimed at the possible development of a relationship with a tertiary pediatric program.

Our hospital is a component of HealthEast, Inc., a 1,031-bed system. Its Pediatrics Department includes a 28-bed Pediatric Unit and a 20-bed Level III Regional Neonatal Intensive Care Unit. There are 38 pediatricians on the staff of the hospital, 11 of whom are subspecialists. The pediatricians care for over 3,000 newborns each year.

Located in a prosperous and desirable area of Pennsylvania, Allentown is one hour from Philadelphia, one and one-half hours from New York City and close to the beautiful Pocono Mountains.

Interested candidates should submit their curriculum vitae in confidence to: **Martha A. Lusser, M.D., Chair, Search Committee, c/o HealthSearch, 50 College Drive, Allentown, PA 18104 or call (215) 778-7993 for descriptive brochure.**

Equal Opportunity Employer M/F/H/V

Professional Opportunities

BC/BE PEDIATRICIAN to join thriving practice in Jacksonville, Florida suburb. Competitive salary plus incentives and partnership opportunity including building ownership. Liberal time off and excellent benefits. Send CV to: Mark Goldschmidt, MD, 1409 Kingsley Avenue, Suite 9-G, Orange Park, FL 32073.

TEXAS — PEDIATRICIAN. Unique opportunity for a pediatrician in offices next to our new replacement hospital in the high-growth section of Abilene, Texas. Immediate referrals and attractive financial assistance. Abilene, located 150 miles west of Dallas/Ft. Worth, is the heart of a 22-county trade area and is home to three universities and Dyess AFB. Send CV to: Manager, Professional Relations, Humana Inc., Department ADC-10, 500 West Main Street, Louisville, KY 40201-1438. Or call toll-free: (800) 626-1590.

ATTENTION PHYSICIAN RECRUITERS. The "Classified Advertising" sections now in all nine AMA Specialty Journals target the physician you want. These highly visible sections put your message in the hands of every specialist that qualifies for your professional opportunity, every month. To place the ad of your choice, any size, call toll free: (800) 237-9851; or in Florida (800) 553-8288.

Faculty Positions

SOUTHEAST USA — Academic Pediatrician. Teach medical students and family practice residents. Direct patient care and clinical research interests required. Alabama State medical license required. Should be board-eligible or board-certified. The University of Alabama is an equal opportunity/affirmative action employer. Send inquiries with CV to: David C. Hefelfinger, MD, Department of Pediatrics, 700 University Boulevard East, Tuscaloosa, AL 35401. (205) 348-1304.

Faculty Positions

BIOSOCIAL ASPECTS OF FAMILY HEALTH: Position available for a tenure ladder faculty member in the Division of Population and Family Health, Department of Community Health Sciences. Applicants must have a PhD, MD, Dr. PH, DSW or other doctorate in field related to public health. Primary responsibilities will include participation in the teaching and research programs in family health, oriented to the USA with emphasis on child health policy and advocacy. In addition, the faculty member should have expertise in one or more of the following areas: children with special health needs, such as developmental disabilities or chronic illness and socio-political factors influencing child health programs and policy in the U.S. It is desirable that the candidate should have had experience in cross-cultural circumstances in the USA. Academic rank and salary will be based on appropriate qualifications and experience and are subject to AAU guidelines. However, assistant professor level applicants are encouraged to apply. Applicants should send cover letter and curriculum vitae to: Charlotte G. Neumann, MD, MPH, Chair Search Committee, Division of Population and Family Health, School of Public Health, University of California at Los Angeles, Los Angeles, CA 90024-1772. Applications deadline: January 15, 1990 and position would start in Fall 1990 or sooner if possible. The University of California is an affirmative action/equal opportunity employer and welcomes applications from qualified women and minority candidates.

Practices For Sale

SELLING YOUR PRACTICE? The AMA journal in your specialty is your best place to advertise. Now available are very affordable ads that are perfect for finding a buyer. Also, Box service is available for your convenience and confidentiality. Call our "Classified Advertising" office toll free: National (800) 237-9851; in Florida (800) 553-8288.

Announcing

The Eleventh Annual
American Medical Association

Morris Fishbein Fellowship

July 2, 1990 through
June 28, 1991

Applications are now being taken for the Eleventh Annual Morris Fishbein Fellowship in Medical Journalism sponsored by the American Medical Association. Physicians interested in

making a substantial commitment to medical journalism are invited to apply for this full-time one-year fellowship program.

Work With JAMA The successful candidate will work with the editorial and production staff of The Journal of the American Medical Association in all facets of editing and publishing a major weekly medical journal. At the completion of the program, it is expected that the candidate will be proficient in all aspects of manuscript selection, issue makeup, copy editing and styling, art and layout of articles, issue planning and managing, in addition to the many other elements of journal publication. He/she will also be conversant with marketing and advertising procedures.

Publishing The candidate must have proved writing ability at the time of application, for he/she will be required during the course of the year to prepare such articles for publication as may be assigned. Although the fellow will work under the supervision of a physician-editor, ability to work independently is a must. Ability to use a resource library is a strong plus.

Specialty Journal Opportunity In addition to The Journal of the American Medical Association, the Fishbein Fellow will receive special insight into the different aspects of publishing a major specialty journal on a monthly timetable.

Stipend A stipend of \$30,000 will be provided to the successful candidate to cover the 1-year period.

Application Forms For an application blank, please write to: Helene M. Cole, MD, Senior Editor, Director, Department of Editorial Affairs, Journal of the American Medical Association, 535 N. Dearborn St., Chicago, IL 60610.

Deadline For Applying Completed applications should be forwarded as soon as possible and must be received no later than January 15, 1990. The successful candidate will be notified by April 2, 1990.

Now the first name in baby food is the new name in formula.

New Gerber™ Baby Formula has a nutrient balance that has been successfully fed to millions of babies.

The 82:18 casein/whey protein composition is one that is exceptionally well tolerated by babies. In a recent clinical study, babies fed the Gerber™ Baby Formula formulation not only tolerated it well—consistent with historical controls—but had similar measurements of growth and development to those fed breast milk and milk-based formulas.¹

Breast milk is the best for babies... but no formula is more nutritious than Gerber™ Baby Formula.

Gerber™ Baby Formula closely resembles average breast milk in micronutrient composition. It also is formulated to provide the levels of nutrients specified by the Infant Formula Act.

Gerber™ Baby Formula Nutrient Sources

Protein – Nonfat milk 82:18 casein/whey

Fat – All vegetable oil

CHO – Lactose

Reference

1. An evaluation of casein-based infant formula in newborns from birth until four months of age. Data on file.

Three generations of babies have thrived on Gerber products.

For over 60 years, the Gerber name has been one that mothers and doctors trust. And we want to assure you that, because mothers trust Gerber, we have included in all our advertising our belief and yours that mother's milk is the ideal first food for babies. After three generations, the name Gerber has become synonymous with quality, consistency, and care.

Gerber™ Baby Formula is available as low-iron and iron-fortified infant formula.

Each comes in three forms:

ready-to-use liquid,
concentrated liquid,
and powder.

For more information call 1-800-828-9119.

A DIVISION OF ABBOTT LABORATORIES, USA

RICHARD W. GAST
PRESIDENT

... on the consumer promotion of infant formula.

There is a development that undermines your control over the infant's diet and health, and that undermines breastfeeding—the advertisement of formulas directly to the mother through TV, magazines and mail.

On June 1, the President of the American Academy of Pediatrics sent a letter to all Fellows of the Academy reaffirming its stance against consumer advertising, and expressing concern that other formula companies might follow Nestlé/Carnation.

This concern was justified. On June 15, it was announced at a press conference that Mead Johnson/Bristol-Myers will be producing an infant formula to be sold and marketed under the Gerber label. Part of the program is a multimillion-dollar budget for advertising the formula directly to mothers via TV and print.

Speaking at the press conference, Gerber Products Division President Robert L. Johnston, Jr., said that Gerber was entering the market because it had, "identified significant changes in usage that convinced us the timing was right. ..."

"First," he said, "there is a rapid decline in breast-feeding after mothers leave the hospital." And, "... parent decision regarding baby formula brand selection has grown. ..."

The irony is inescapable and appalling. In other words, because breastfeeding is declining, more infant formulas should be promoted to the mother. In other words, because some mothers are making feeding decisions on their own, even more mothers should follow suit.

When Nestlé/Carnation entered the marketplace and, again, when Mead Johnson/Bristol-Myers joined with Gerber, we reexamined the Ross philosophy of promoting SIMILAC® Infant Formulas. The result of our deliberations was an even deeper resolve to support the doctor/patient relationship.

Our philosophy remains unchanged. Ross Laboratories has no plans to resort to direct consumer advertising for SIMILAC and our other infant formula products.

We will continue as an ally of health care professionals by supporting your prerogative to prescribe and recommend products as training and experience dictate.

We stand behind you.

Richard W. Gast

The AMERICAN JOURNAL OF DISEASES OF CHILDREN is a member of the consortium of AMA journals listed below. The Archives reaches more than 41 500 readers in 85 countries each month. The complete text of all AMA journals is available on the MEDIS data base from Mead Data Central, Dayton, Ohio.

Triaminic® Nite Light™

**For 8 full hours of nighttime
cough relief for children...**

**Helps children with coughs and colds get the relief
they need...and helps parents rest easier!**

Now, a single bedtime dose of Triaminic NITE LIGHT is all it takes for 8 hours of relief from persistent nighttime cough — often the most troublesome symptom a child suffers.

The maximum pediatric dose of dextromethorphan helps ease nighttime cough while a decongestant and an antihistamine temporarily relieve other cold symptoms that can deprive a child of much-needed sleep.

Recommend Triaminic® NITE LIGHT™, a good night from Triaminic®

EDITORIAL POLICY

The JOURNAL is meant to provide physicians in all specialties who practice pediatric medicine a complete and accurate synthesis of all current research developments and clinical topics pertinent to their practice, as well as an open forum for dialogue on scientific, educational, ethical, and humanistic issues of concern to any intellectual committed to the practice of pediatrics.

YOUR POWERFUL ALLY AGAIN

**IMMUNE RESPONSE INCLUDES
FUNCTIONALLY IMPORTANT
ANTIBODY PRODUCTION
FOLLOWING IMMUNIZATION
WITH ProHiBiT®.***

**Immunologic
memory:**
ProHiBiT®
primed memory
cells are armed
to produce
antibodies in
response to
Haemophilus b
polysaccharide
antigen.

**2. Complement
fixation:**
ProHiBiT®
induced
antibody fixes
complement,
damaging the
bacterial cell
wall membrane.

HAEMOPHILUS b DISEASE.

3. Opsonic activity:
ProHIBiT® induced antibody stimulates circulating leukocytes to phagocytize bacteria.

DEFENDS

ProHIBiT® defends against Haemophilus b disease in three important ways:

1

PRIMES

THE IMMUNE SYSTEM

ProHIBiT® primes the immune system to produce memory cells that stimulate rapid production of antibodies when challenged^{1,2} with native polysaccharide.

2

PROMOTES

BACTERICIDAL ACTION

ProHIBiT® promotes bactericidal action² of the immune system to help your patients fight off infection.

3

ENHANCES

PHAGOCYTOSIS

ProHIBiT® induced antibody enhances phagocytosis² (opsonic activity).

If you wish to order ProHIBiT®, call the following toll-free number: 1-800-VACCINE (1-800-822-2463).

Connaught Laboratories, Inc.

ProHIBiT®

**Haemophilus b Conjugate Vaccine
(Diphtheria Toxoid-Conjugate)**

**PROVEN SAFE AND WELL TOLERATED
AFTER MILLIONS OF IMMUNIZATIONS¹**

Please see brief summary of prescribing information on last page of this advertisement.[†]

*ProHIBiT® is currently indicated for children 18-60 months of age.

[†]Serious adverse experiences (seizures, Guillain-Barré syndrome), have been rarely reported in association with ProHIBiT® immunization.

ProHIBiT[®]

YOUR POWERFUL ALLY AGAINST HIB DISEASE

Haemophilus b Conjugate Vaccine (Diphtheria Toxoid-Conjugate)

Caution: Federal (U.S.A.) law prohibits dispensing without prescription.

BRIEF SUMMARY

INDICATIONS AND USAGE

ProHIBiT is indicated for the routine immunization of children 18 months to 5 years of age against invasive diseases caused by *Haemophilus influenzae* type b. As with other vaccines, several days following administration of ProHIBiT are required for protective levels of antibody to be attained.

A booster dose of ProHIBiT is *not* required.

ProHIBiT will not protect against *Haemophilus influenzae* other than type b or other microorganisms that cause meningitis or septic disease.

No impairment of the immune response to the individual antigens was demonstrated when ProHIBiT and Diphtheria and Tetanus Toxoids and Pertussis Vaccine Adsorbed (DTP) were given at the same time at separate sites.

Because the safety and efficacy of ProHIBiT have not been established in children less than 18 months of age, ProHIBiT is not indicated for use in this age group at this time. Studies to establish the safety and efficacy of ProHIBiT in children less than 18 months of age are ongoing.

ProHIBiT IS NOT RECOMMENDED FOR USE IN CHILDREN YOUNGER THAN 18 MONTHS OF AGE.

CONTRAINDICATIONS

HYPERSENSITIVITY TO ANY COMPONENT OF THE VACCINE, INCLUDING THIMEROSAL AND DIPHTHERIA TOXOID, IS A CONTRAINDICATION TO USE OF THIS VACCINE.

WARNINGS

If ProHIBiT is used in persons with malignancies or those receiving immunosuppressive therapy or who are otherwise immunocompromised, the expected immune response may not be obtained.

As with any vaccine, ProHIBiT may not protect 100% of individuals receiving the vaccine.

PRECAUTIONS

GENERAL

As with the injection of any biological material, Epinephrine Injection (1:1000) should be available for immediate use should an anaphylactic or other allergic reaction occur.

Prior to an injection of any vaccine, all known precautions should be taken to prevent adverse reactions. This includes a review of the patient's history with respect to possible hypersensitivity to the vaccine or similar vaccines.

Any febrile illness or acute infection is reason to delay the use of ProHIBiT.

As reported with *Haemophilus b* polysaccharide vaccine, cases of *Haemophilus b* disease may occur in the week after vaccination, prior to the onset of the protective effects of the vaccine.

Special care should be taken to ensure that the injection does not enter a blood vessel.

A separate, sterile syringe and needle or a sterile disposable unit should be used for each individual patient to prevent transmission of hepatitis or other infectious agents from one person to another.

ALTHOUGH SOME IMMUNE RESPONSE TO THE DIPHTHERIA TOXOID COMPONENT MAY OCCUR, IMMUNIZATION WITH ProHIBiT DOES NOT SUBSTITUTE FOR ROUTINE DIPHTHERIA IMMUNIZATION.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY

ProHIBiT has not been evaluated for its carcinogenic, mutagenic potential or impairment of fertility.

PREGNANCY

REPRODUCTIVE STUDIES — PREGNANCY CATEGORY C

Animal reproduction studies have not been conducted with ProHIBiT. It is also not known whether ProHIBiT can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. ProHIBiT is NOT recommended for use in a pregnant woman.

ADVERSE REACTIONS

When ProHIBiT alone was given to over 1,000 adults and children, no serious adverse reactions were observed. Thrombocytopenia was seen in one adult but a causative relationship was not established.

When ProHIBiT was given with DTP and Inactivated Poliovirus Vaccine to 30,000 young infants, the rate and extent of serious adverse reactions were not different from those seen when DTP was administered alone. Allergic reactions such as urticaria were infrequently observed.

Selected adverse reactions following vaccination with ProHIBiT (without DTP) in subjects 16-24 months of age are summarized in Table.

TABLE				
Percentage of Subjects 16-24 Months of Age Developing Local Reactions or Fever to One Dose of Haemophilus b Conjugate Vaccine (Diphtheria Toxoid-Conjugate)				
	No. of Subjects*	Reaction %		
		6 Hours	24 Hours	48 Hours
Fever >38.3°C	281	1.1	2.1	1.8
Erythema	285	—	2.5	0.4
Induration	285	—	1.0	0.4
Tenderness	285	—	4.6	0.7

*Not all subjects had measurements at all time periods.

Other adverse reactions temporally associated with administration of ProHIBiT included diarrhea, vomiting, and crying and occurred at a frequency of ≤1.2%.

Adverse reactions in clinical evaluations among 689 children, 7-14 months of age, 24 hours after receiving a single dose of ProHIBiT, were observed and compared to 139 children who received a saline placebo. There were no significant differences in the reaction rates for fever, erythema, induration, and tenderness between the two groups.

DOSAGE AND ADMINISTRATION

Parenteral drug products should be inspected visually for extraneous particulate matter and/or discoloration prior to administration whenever solution and container permit. If these conditions exist, vaccine should not be administered.

ProHIBiT is indicated for children 18 months to 5 years of age. The immunizing dose is a single injection of 0.5 ml given intramuscularly in the outer aspect area of the vastus lateralis (mid-thigh) or deltoid.

Each 0.5 ml dose contains 25 mcg of purified capsular polysaccharide and 18 mcg of conjugated diphtheria toxoid protein.

Before injection, the skin over the site to be injected should be cleansed with a suitable germicide. After insertion of the needle, aspirate to ensure that the needle has not entered a blood vessel.

DO NOT INJECT INTRAVENOUSLY.

HOW SUPPLIED

Vial, 1 Dose (5 per package) — Product No. 49281-541-01

Vial, 5 Dose — Product No. 49281-541-05

Vial, 10 Dose — Product No. 49281-541-10

STORAGE

Store between 2°-8°C (35°-46°F). DO NOT FREEZE.

NEW MANUSCRIPT PROCEDURE

On January 1, 1988, *AJDC* initiated a new procedure. Manuscripts submitted to *AJDC* will NO LONGER BE RETURNED, except in the case of accepted manuscripts or those undergoing author revision. Original artwork and photographs will be returned.

General Information.—Please send manuscripts and correspondence by first-class mail (do not use registered, certified, or express mail) to the Editor, Vincent A. Fulginiti, MD, *AJDC*, Dean's Office, Room 1529, Tulane University, School of Medicine, 1430 Tulane Avenue, New Orleans, LA 70112. All accepted manuscripts are subject to copy editing. The corresponding author will receive an edited typescript and layout for approval. Forms for ordering reprints are included with the edited typescript. Reprints are shipped six to eight weeks after publication. Proofs will be sent for approval if requested by the author and if printing deadlines permit. The author is responsible for all statements in his/her work, including changes made by the copy editor.

Conforming with all of the steps listed below will facilitate the editorial processing of your manuscript.

Step 1.—Cover Letter.—All manuscripts must be accompanied on submission by a cover letter giving the name, address, affiliation, and telephone number of the corresponding author. The letter must include ALL of the following statements SIGNED BY ALL AUTHORS (ORIGINAL SIGNATURES):

1. **Copyright Release.**—"In consideration of the American Medical Association's taking action in reviewing and editing this submission, the author(s) undersigned hereby transfer(s), assign(s), or otherwise convey(s) all copyright ownership to the AMA in the event that this work is published by the AMA."

2. **Statement of Affirmation.**—"This manuscript has not been published anywhere in any language and is not under simultaneous consideration by another publication. This manuscript is original and ALL authors have seen and approve of its contents."

3. **Financial Disclosure.**—List all affiliations with or financial involvement in organizations or entities with a direct financial interest in the subject matter or material of the research discussed in the manuscript (eg, employment consultancies, stock ownership) OR include a statement disclaiming any such involvement. All such information will be held in confidence during the review process. Should the manuscript be accepted, the Editor will discuss with the author the extent of disclosures appropriate for publication. All accepted manuscripts become the permanent property of the publisher (AMA) and may not be published elsewhere without written permission from the AMA. After publication certain articles may appear in translation in the foreign-language edition(s) of *AJDC*.

Step 2.—Manuscript Format.—All articles submitted should have the following features:

1. Four copies of the manuscript should be submitted; three are for transmission to referees and one is to be retained in the editorial office. We prefer an original and three copies.

2. Manuscripts should be typed in triple-spaced format on heavy-duty white bond paper, 21.6 × 27.9 cm (8½ × 11 in) with 2.5-cm (1-in) margins. Do not use justified right margins.

3. Title should be no more than 75 characters.

4. Authors should be limited to six, all of whom have contributed to the study and manuscript preparation, are familiar with its substance, and are able to defend its conclusions.

5. The title page should give full names, degrees, and academic affiliations of all authors, address for request of reprints, and, if the manuscript was presented at a meeting, the organization, place, and exact date on which it was read.

6. Writing style should conform to proper English usage and syntax; consult the *American Medical Association Manual of Style*, available from Williams & Wilkins, 428 E Preston St, Baltimore, MD 21202.

7. Abstract should be limited to 135 words or less.

8. Each table should be typed, with a title, on a separate sheet of paper, with each line, including headings, double-spaced. Continuations should be on a second sheet with all headings repeated.

9. Use Systeme International (SI) measurements throughout the manuscript.

10. Illustrations should be high-contrast, glossy prints, in quadruplicate, unmounted and untrimmed; lettering should be legible after reduction to column size. Figure number, name of first author, and arrow indicating top should be typed on a gummed label and affixed on the back of each illustration. Do not write directly on the print.

Magnification and stain should be provided for histologic sections. Full-color illustrations should be submitted as 35-mm, positive color transparencies, mounted in cardboard and carefully packaged. Do not submit glass-

fee must accompany submission.

All photographs in which there is a possibility of patient identification should be accompanied by a signed statement of consent from both parents (or guardians). Covering eyes to mask identity is not sufficient.

11. References should be listed in order of their appearance in the text, type double-spaced, and in AMA format. Please follow the exact order of information and punctuation in the examples below. Note: List all authors and/or editors up to six; if more than six, list the first three and "et al."

Journal articles: Scott GB, Buck BE, Leterman JG, Bloom FL, Parks WP. Acquired immunodeficiency syndrome in infants. *N Engl J Med*. 1984;310:76-81.

Books: Naeye RL. How and when does antenatal hypoxia damage fetal brains? In: Kubli F, Patel N, Schmidt W, Linderkamp O, eds. *Perinatal Events and Brain Damage in Surviving Children*. New York, NY: Springer Verlag NY Inc; 1988:83-91.

Unpublished data, personal communications, or manuscripts "in preparation" or "submitted" should not be included in the list of references. Such material, if essential, may be incorporated in the body of the article.

Authors are responsible for the accuracy of the references.

12. Investigations involving human subjects require a specific statement in the "Methods" section that an appropriate institutional review board approved the project and/or that informed consent was obtained from both legal guardians and/or child, if appropriate.

13. Illustrations and tables from other publications should be suitably acknowledged, with written permission from publisher and author. Brief acknowledgements to specific contributors directly involved in the content of the manuscript may be placed at the end of the text, before the references. General acknowledgements will be deleted.

Step 3.—Special Departments.—Criteria for several special departments are given below.

1. **The Pediatric Forum.**—This is the place for comment, criticism, observations, and discussion of "issues of current concern and importance for children's health," in addition to letters that comment on articles in previous issues of *AJDC*. The Editor reserves the right to conduct review of and to edit all submissions. THE READER SHOULD SUBMIT TRIPLE-SPACED COPY CLEARLY MARKED "FOR PUBLICATION" AND SIGNED BY ALL AUTHORS. REFERENCES, IF INCLUDED, SHOULD CONFORM TO THE USUAL AMA FORMAT. Copyright assignment, signed by all authors, must accompany the original submission.

2. **From Research to Relevance.**—PURPOSE: To focus on significant research that has a high probability of being translated into clinical usefulness.

3. **Educational Interventions.**—PURPOSE: To share information concerning any educational efforts in the broad field of pediatrics.

4. **Sports Medicine.**—PURPOSE: To provide current information related to the medical needs of young athletes, as pertinent to counseling young athletes and their parents regarding sports participation and practices contributing to the health maintenance of the athlete, as well as current concepts in the prevention, diagnosis, and treatment of sports-related illnesses and injuries.

5. **Picture of the Month.**—Submissions should be sent directly to Murray Feingold, MD, National Birth Defects Center, Kennedy Memorial Hospital, 30 Warren St, Brighton, MA 02135, and should conform to the format for original articles in terms of the text, references, and illustrations.

6. **Radiological Case of the Month.**—Submissions should be sent directly to Beverly P. Wood, MD, University of Rochester Medical Center, 601 Elmwood Ave, PO Box 648, Rochester, NY 14642. Submissions should conform to the format for original articles in terms of the text, references, and illustrations.

Author's Checklist

- 1. Cover letter with name, address, and telephone number of corresponding author.
- 2. Copyright transmittal, affirmation, and financial statements signed by ALL authors.
- 3. Original typed manuscript plus three copies.
- 4. Triple-spacing; double-spacing for tables and legends.
- 5. Right margins UNJUSTIFIED.
- 6. Title 75 characters or less.
- 7. Abstract included.
- 8. References in proper format, cited in numerical order.
- 9. Four sets of illustrations.
- 10. Four sets of legends for illustrations.
- 11. Proper consent forms for patient photographs.
- 12. Permission forms for illustrations previously published elsewhere.

This department of AJDC is reserved for comment, criticism, observation, and discussion of "issues of current concern and importance for children's health." The Editor encourages our readers to express themselves on a variety of topics and issues. Further, we encourage the submission of unique and brief clinical and scientific observations that do not fulfill the criteria for original articles.

Stress Experienced During Pediatric Residency Training Program

Sir—I write to laud the articles by Hoekelman¹ and Cohen and colleagues² in the February 1989 issue of *AJDC*. In looking at the balance between the financial needs of young people in pediatric training and the financial distress that institutions increasingly are incurring and are going to incur to an even greater degree, one wonders whether, in addition to some of the solutions suggested by the above authors, pediatric residency training should be changed, both at the training program level and at the American board level.

Of the total 3 years in pediatric residency at our institution, 3 months are spent on vacation and 6 months are spent in "electives." Of these electives, one is psychosocial and of definitive value in future practice. On the other electives, the resident acts as a junior fellow, by and large, doing the initial consultation on the patient for the fellow and then trailing the fellow and then the attending staff around the institution. The resident is seeing the same patients that he or she would have seen if carrying out patient care duties in the institution and, indeed, is seeing the same fellows or faculty that he or she sees on the pediatric electives. Despite this and despite the problems with stress during training programs and the need for what Cohen and colleagues call "humane and flexible training programs," the Accreditation Council for Graduate Medical Education (ACGME) requires a certain number of rotations in subspecialties accredited by the council for a residency program to be accredited and, indeed, for the resident to experience before he or she graduates.

There is a certain self-serving cravenness in this whole business. I seriously doubt that residents go into gastroenterology, hematology, or car-

diology because of a 1-month elective. I wish that there were ways to prove this, but in the climate of decreasing dollars, increasing stress, and problems with house staff training, I wish that ACGME and all of the training program directors would look carefully at the value and need for electives of any kind. Eliminating such electives would have to be done across the board in every program, ie, each program would have to require that there be no electives, or the programs could not be competitive. If that were done and residents were allotted to programs based on pediatrics and the pediatric subspecialties on ward rotations and in the outpatient department, I think that there would be time to both reduce the stress and make the programs more flexible to meet the ultimate goals of residency training. Personally, I think that residents could achieve staff role models much better from a continuous staff ward rotation than they presently achieve from what are often very ill-defined elective rotations.

I suggest this as one way to look at the entire problem of stress during residency training programs vs dollars required to pay residents to complete 3 years of pediatric training.

Use of Intravenous Immunoglobulin in the Treatment of Neonatal Sepsis

The mortality and morbidity associated with neonatal sepsis and meningitis remain significant despite ad-

vances in antimicrobial chemotherapy and supportive care. Recent studies have shown that administration of a specific antibody in conjunction with antibiotics may improve the outcome of neonates with sepsis. For example, Shigeoka et al¹ showed that infants infected with group B streptococci and transfused with whole blood containing specific opsonic antibody had significantly improved survival compared with infants receiving blood lacking antibody to the infected strains. The feasibility of this combined immunotherapy and antimicrobial chemotherapy has been aided by the availability of safe preparations of human intravenous immunoglobulin (IVIG).

In contrast to conventional intramuscular immune serum globulin, IVIG can be given in large quantities to patients, regardless of body size or muscle mass, thereby providing immediate high levels of specific antibody that may be of therapeutic benefit. Two prospective control studies have been published concerning the use of IVIG in the treatment of neonatal sepsis (Table). Both studies reported that treatment with IVIG and antibiotic therapy significantly improved the survival of premature infants with sepsis compared with antibiotic therapy alone.^{2,3}

Two studies were subsequently cited as an important observation for the therapeutic potential of IVIG in neonatal sepsis.⁴ However, both studies suffered from improper statistical analysis. The Student *t* test was applied in the report of Haque et al³ for calculating the difference in the outcome, and there was no mention of specific statistical methods employed in the report of Sideropoulos et al.² Similarly, both studies failed to specify whether they were testing the null hypothesis or an alternative hypothesis.

To test the null hypothesis that there is no difference between the treatment regimens, a two-tailed

Efficacy of IVIG* in the Treatment of Neonatal Sepsis				
IVIG	Mortality, No. (%) of Patients		P†	
	IVIG	No IVIG	Reported	Corrected
pH4-treated IVIG, 1 g/d for full-term infants	1/7 (14)	0/6	NS	NS
pH4-treated IVIG, 0.5 g/d for premature infants for 6 d	1/13 (8)	4/9 (44)	.04‡	.13§
Total	2/20 (10)	4/15 (27)	NS	NS
IgM-enriched IVIG, 0.25 g/kg per d for premature infants for 4 d	1/30 (3.3)	6/30 (20)	<.001	.10§

*IVIG indicates intravenous immunoglobulin.

†NS indicates not significant.

‡Statistical methods not specified.

§Two-tailed Fisher's Exact Test.

||Student's t test.

Fisher Exact Test should have been used to analyze their data. As shown in the Table, using this revised statistical analysis, both studies showed a trend but no statistically significant differences were evident between IVIG with antibiotic therapy vs antibiotics alone.

Thus, at present, the therapeutic efficacy of IVIG for neonatal sepsis is not clear. Experimental studies have revealed that IVIG plus antibiotic therapy were beneficial in rapidly clearing bacteria from the bloodstream or in improving survival in newborn rats infected with group B streptococci or *Escherichia coli*.^{5,6}

Although IVIG has been used in many infants with sepsis on a compassionate basis, further use of this form of therapy requires carefully conducted controlled studies. These studies should also provide information on many unsettled issues concerning the therapeutic use of IVIG in neonatal sepsis, such as functional activity against common neonatal pathogens, effective optimal dose, and the potential hazards with the use of higher doses.⁷ Until data from such studies demonstrate a clear-cut benefit, a widespread prescription of IVIG in the treatment of neonatal sepsis should be restrained.

Theophylline and School Performance

Sir.—In their article in the April 1989 issue of *AJDC*, Gutstadt et al¹ reported that the low scores on standardized tests of reading and mathematics obtained by their 99 patients were significantly associated with low socioeconomic status, older age, a history of continuous steroid use, and the presence of emotional and behavioral problems. With respect to the latter finding we were surprised that even though 94 of their 99 moderately to severely asthmatic patients were being treated with theophylline, the authors made no mention of a possible association between the use of theophylline and emotional or behavioral

problems. We think that the omission of this information is important because the impression given is that the only medications among the many that these patients were taking that might have had a negative effect on their academic performance were their steroids when, in fact, theophylline's effect on their performance may have been equally significant.

Previous studies, including our own have found theophylline usage to be related to problems in visual-spatial planning, concentration, hyperactivity, depression, and anxiety. In light of such findings it seems reasonable to conclude that theophylline may be a significant determinant of school performance in children with chronic asthma as any of those identified by Gutstadt and her colleagues.

1. Gutstadt LB, Billette JW, Mrazek DA, Fukuhara JT, LaBrecque JF, Strunk RC. Determinants of school performance in children with chronic asthma. *AJDC*. 1989;143:471-475.

In Reply.—The major finding of our study was that children with moderate to severe asthma had average to slightly above average scores for academic performance. Only a small percentage of children scored less than 1 SD below the mean for either reading or math. Having performance score at the lower end of these relative normal values did correlate with certain features of the asthma, as reiterated by DuHamel and Furukawa in their letter. A number of other variables defining asthma and its treatment, including "medication being taken at the time of the evaluation" were considered, but "did not correlate with performance" (p 474). Use of theophylline medication was recorded (Table 1, p 472) and included in the analysis. Theophylline medication may not have correlated with performance because such a high percentage (94%) of the children were using the medication. It is also possible that theophylline had an effect on performance, but was mediated through changes in behavior and was not a

parent directly. However, it seems likely that theophylline medication may not play a major role in determining academic performance in children receiving treatment with multiple medications for control of asthma, especially if there are emotional and behavioral problems that result from difficulties adjusting to the chronic illness.

Ischemic Injury and Necrotizing Tracheobronchitis

Sir.—The article by Hanson et al¹ in the October 1988 issue of *AJDC* somewhat supported a personal belief that ischemic injury is involved in the propagation of necrotizing tracheobronchitis (NTB). However, I do not believe that their data justify a causal relationship, as the title of the article would imply. Although 58 infants with NTB had either profound hypotension or low 5-minute Apgar scores (the "ischemia" factors that differentiated them from the controls), the remaining 64 affected infants (54%) had neither of these factors. Furthermore, the authors state that their data were analyzed with "a two-tailed *t* test."¹ I suspect that they actually meant that χ^2 analysis was used. Simplistically, the *t* distribution is a method of comparing two group means, while the χ^2 statistic compares rates or frequencies of discrete findings. The *P* values presented in the tables are actually those that one would calculate using χ^2 analysis. Furthermore, since multiple comparisons of various factors are made, there is a greater likelihood of a type II error. To avoid this possibility, a number of multiple comparison procedures or adjustments are available (Bonferroni's, Tukey's, Student-Neuman-Keuls', etc). However, since the authors are individually evaluating a number of possible risk factors to ascertain causal relationships with NTB, multivariate analysis would be a better tool. One only has to examine their hypotension and 5-minute Apgar score data to realize the inadequacy of their method of analysis. One hundred twenty-two infants had NTB. Forty of these infants had 5-minute Apgar scores of 7 to 10 and subsequently developed profound hy-

potension. Of the 82 infants with lower 5-minute Apgar scores (0 to 6), only 4 developed severe hypotension. By statistically comparing these factors as the authors do their other data, $P < .0005$ is generated, and one could conclude that high 5-minute Apgar scores cause severe hypotension. Obviously, other confounding variables have to be considered. Again, multivariate analysis would represent a method of analyzing independent risk factors for causal relationships.

Hanson et al used a modified version of the scoring system of Joshi et al² to grade histologic changes. We are aware of at least four other scoring systems that attempt to quantitate airway injury.³ Our system provides a consistent, reproducible evaluation of histologic alterations.³⁻⁶ Unfortunately, the lack of a generally accepted "standard" system makes comparisons of the various studies difficult.

deLemos et al⁷ have previously postulated that NTB represents an ischemic injury related to intraluminal tracheal pressure effects on mucosal and submucosal blood flow. The concept presented by Hanson et al of tracheal perfusion pressure is a similar hypothesis. Mean airway pressure is a key part of their theory. Unfortunately, in their report they did not examine the effect of mean airway pressure on the propagation of injury. Furthermore, peak inspiratory and end-expiratory pressures were only compared in 22 of 206 infants. If such information were available, the validity of their concept could be addressed. We have also found greater damage in the upper tracheae of subjects undergoing ventilation as well as numerous "skip" areas of injury throughout the airway.⁴⁻⁶ These findings have led us to speculate that intraluminal elements that directly traumatize epithelial surfaces may also influence airway histologic changes.

Multiple mechanisms have been proposed as potential causes of the extensive damage of NTB. However, to date there have been few investigations evaluating the relative contribution of individual factors.^{4-6,8,9} Anecdotal reports or retrospective reviews can identify correlations, but they cannot establish causality. In our clinical experience, as well as in that of others,¹⁰⁻¹² NTB occurs in the most severely ill infants, frequently following a course complicated by asphyxia, hypotension, and high ventilator settings. These features led us to in-

vestigate the roles of hypotension, hypoxemia, and "high" vs "low" ventilator settings in the propagation of tracheobronchial injury during conventional mechanical ventilation.⁶ Using a newborn piglet model, we found that a combination of hypotension and hypoxemia led to more extensive histologic changes than either factor alone. Furthermore, high ventilator settings alone were not associated with more damage than low settings. Surprisingly, higher mean airway pressures did not influence the degree of changes. As Hanson et al have suggested, their theory of tracheal perfusion pressure requires further investigation.

Hanson et al are to be commended for bringing to light the very frequent pathologic finding of airway injury in infants undergoing conventional ventilation. Mammel and Boros¹³ reported that 91% of infants who die following high-frequency jet ventilation have histologic evidence of NTB at autopsy. The determinants of NTB must be identified before we can hope to modify or avoid this entity.

Hematologic Syndrome of Growth-Retarded Infants

Sir.—The article by Philip and Tito¹ in the February 1989 issue of *AJDC* was pleasant reading. Their finding of increased nucleated red blood cell (NRBC) counts in small-for-gestational age (SGA) infants, not uncommonly associated with thrombocytopenia and leukopenia, corresponds very well with our own data.² Their hypothesis for the pathogenesis behind the increased NRBC counts (chronic hypoxemia) is also in accordance with ours. Their discussion, however, seems to me rather descriptive. They do not comment on the low platelet and leukocyte counts, and do not offer any deeper explanation for possible mechanisms.

Intrauterine growth retardation is often caused by placental malfunction, leading to long-lasting intrauterine hypoxemia and stimulation of fetal erythropoiesis. This increases output of erythroblasts to the circulation, and is successively followed by polycythemia. Air breathing after birth brings the hypoxemic condition to an end. In our patients the erythroblasts disappeared from circulation during the first week of life, while thrombocyte counts usually normalized 10 to 15 days after birth.² Experimental studies, exposing pregnant animals (mice) to persistent hypobaric hypoxemia, reproduced the growth retardation, polycythemia, and transient thrombocytopenia in the offspring.³ Studies on humoral regulation of erythropoiesis pointed to a compensated state of tissue oxygenation in most SGA infants and experimental animals because erythropoietin values were normal in the presence of an increased oxygen transport capacity (polycythemia).^{4,5} Small-for-gestational age infants had normal levels of thrombopoietin, indicating no lack of humoral drive for thrombopoiesis.⁴

In my opinion there exists a "hematologic syndrome of the SGA infant" in the early neonatal period. In its full expression this syndrome con-

sists of an increased NRBC count, polycythemia, thrombocytopenia, and a decreased leukocyte count. The different "signs" of this syndrome may be explained by one common pathogenetic mechanism: impaired oxygenation of the fetus. This initiates competition for common stem cells for erythropoiesis, thrombopoiesis, and granulocytopenia in hematopoietic tissue, shunting these stem cells in the direction of erythropoiesis at the expense of thrombopoiesis and granulocytopenia. Experimental studies clearly support such an interdependency between different lines of hematopoietic cell differentiation.⁶

6. Cooper GW, Cooper B. Relationships between platelet and erythrocyte formation. *Life Sci*. 1977;20:1571-1580.

In Reply.—The comments by Dr Meberg provide an opportunity to amplify our discussion and to acknowledge that we had overlooked his article published in 1978.¹ The possibility of selective stimulation of stem cells in the direction of erythropoiesis appealed to us, which is why we reported that thrombocytopenia and leukopenia were not uncommon and associated with increased NRBC counts in SGA infants. We reported in the "Results" section that "Contrary to expectation, SGA infants with marked increase in NRBC counts did not demonstrate high hematocrit values . . ."

As we mentioned, others have noted thrombocytopenia and neutropenia in SGA infants. Brazy et al² noted a high incidence of thrombocytopenia and neutropenia in infants born to mothers with severe hypertension, many of whom (39%) were SGA. McIntosh

et al³ described these findings in association with increased NRBC counts in extremely low-birth-weight SGA infants. They also postulated that marrow stem cells may be more committed to producing cells of the red blood cell series in utero, but noted that no bone marrow studies have been reported in these SGA infants.

One piece of evidence that does not fit neatly with the selective stem-cell stimulation theory deals with hematopoietic progenitors in cord blood. Issaragrisil⁴ showed that although erythroid progenitors correlated well with the number of erythroblasts, so too did granulocyte-monocyte progenitors. However, Christensen et al⁵ have demonstrated in preterm infants that granulocyte-macrophage progenitors may be unable to increase neutrophil production "in times of need," such as bacterial infection, leading to neutropenia. To my knowledge, this has not been evaluated in SGA infants.

Perhaps we did not see elevated hematocrit values because our sights were set too high (>0.60). There is recent evidence that fetal hematocrit values have a mean value of 0.41 between 26 and 30 weeks' gestation,⁶ so values between 0.50 and 0.60 may be elevated. Such levels would not normally be classified as "polycythemia" (erythrocythemia).

Despite these minor reservations, I am inclined to agree with the pathogenetic mechanism proposed by Dr Meberg and also that there probably is a "hematologic syndrome of the SGA infant."

Cat-scratch Disease Therapy

Sir—Since my original experience¹ with cat-scratch disease, I have remained interested in it and impressed with its stubborn resistance to therapy.

During the last 3 months I have treated 11 children (Table) for cat-scratch disease with 20 mg/kg of trimethoprim-sulfamethoxazole twice daily for 7 days, and all 11 have shown prompt improvement. The enlarged nodes were visible, very tender, and firm without palpable suppuration. All of these patients were treated with trimethoprim-sulfamethoxazole twice daily within 7 days of the onset of their enlarged gland. The lymph nodes became nontender in 4 to 6 days, and smaller by 7 to 10 days. They were 10 mm or smaller by 3 weeks in all cases. Nine of 11 patients had a history of exposure to cats. There was a primary inoculation lesion (usually a scratch) in 7 of these 11 patients. My prior experience had been to treat them with penicillins or cephalosporins, and the disease would run the usual 4- to 6-week course. After 1 week the nodes were always the same size or larger. Several patients had previously required needle aspiration of pus after 4 to 6 weeks of continued painful lymph node swelling. None of the 11 recent patients required this.

These patients did not have pharyngitis, significant fever, otitis, or evidence of cellulitis to suggest other causes of lymphadenitis. Blood tests for bacterial and viral titers were not done. It is probably significant that a recently described patient with neutropenia and oculoglandular syndrome finally showed improvement when trimethoprim-sulfamethoxazole was given.² My experience with the disease is in agreement with the reported seasonal incidence,³ finding it to be more common in the fall and more common in Georgia than Long Island, NY. It is the most common cause of painful regional lymphadenitis seen in Georgia. It is thought to be caused by a gram-negative bacteria acquired from cats.^{4,5}

Circumcision and Urinary Tract Abnormalities

Sir—In a study recently published in *AJDC*, Herzog¹ showed that noncircumcision is a significant risk factor for urinary tract infection (UTI) in infants up to 12 months of age, an assertion that supports earlier studies by Wiswell et al.^{2,3} In Herzog's study 8 (26%) of 31 uncircumcised male infants with UTI were found to have anatomic abnormalities detected roentgenographically. It is further pointed out that in three of four previous studies of the incidence of urinary tract abnormalities in infants less than 1 year of age with UTI, the frequency of roentgenographic abnormalities is even greater. Though circumcision status was not mentioned in those studies, "they were from countries where neonatal circumcision is not routine."¹ The implication is that noncircumcision puts an infant at risk for an anatomic abnormality of the urinary tract. This implication is by no means proved and, in fact, can and has been misconstrued, especially in the popular press, as further justification to support newborn circumcision. The eight urinary tract abnormalities detected in Herzog's study—posterior urethral valves, ureteropelvic junction obstruction, two cases of grade IV reflux, and four cases of

*Plus sign indicates positive or present; minus sign, negative or absent.

grade II reflux—were almost certainly present from birth and are likely to have been factors that contributed to the development of UTI rather than the result. In these infants noncircumcision may have been advantageous because it contributed to the development of UTI early in life, prompting roentgenographic investigations that detected an occult urologic abnormality. Noncircumcision status as a known risk factor for UTI may lead to earlier and more appropriate urine sampling from a male infant with fever or any other nonspecific sign of illness. While studies like those of Herzog and Wiswell et al are valuable, they do not justify routine circumcision of the newborn.

3. Wiswell TE, Roscelli JD. Corroborative evidence for the decreased incidence of urinary tract infections in circumcised male infants. *Pediatrics*. 1986;78:96-99.

Sir—In the March 1989 issue of *AJDC*, Herzog¹ presented reports of 36 infants with positive urine culture during routine workup for acute illness. All these infants were uncircumcised, whereas this was true only for 32% of the control population. Of the 31 infants who underwent roentgenographic studies, 4 had grade II and 2 grade IV reflux, 1 had posterior urethral valve with hydronephrosis, and 1 had ureteropelvic junction obstruction and hydronephrosis. The authors concluded that noncircumcision is a highly significant risk factor for UTI in infants.

There is a recent surge of interest and controversy about the association of infantile UTI and periurethral bacterial flora with noncircumcision.²⁻¹⁴ On one side of the spectrum circumcision is considered to be a prophylactic measure against UTI in infants (Wiswell and his collaborators^{3,8,10,13,14}), while on the other, the need to perform surgery on 96 to 98 infants to prevent

two to four UTIs is questioned.⁵⁻⁷ It is also suggested that adequate hygiene could be a less invasive way of preventing UTI than circumcision.⁷ Some opponents of routine circumcision are concerned about the small but existing surgical risk; others focus on the pain associated with the procedure. In addition, the significance of UTI for future complications is not well known.

Based on recent evidence,^{2-4,8} a new Ad Hoc Task Force on Circumcision appointed by the American Academy of Pediatrics is expected to change the previous recommendation¹⁵ so that the potential benefit of circumcision in avoiding infantile UTI is included in the parental information.

From the present study, however, a new conclusion needs to be considered. It appears that noncircumcision has a definite advantage in aiding the early detection of potentially serious anatomical deformities of the genitourinary system by allowing the development of UTI relatively early in the course. In such cases surgical intervention or close medical follow-up may be initiated to ensure better long-term outcome. While 2% to 4% of circumcised boys have the clear advantage of avoiding UTI, a fact of yet uncertain significance, approximately 25% of those 2% to 4% "lucky ones" may turn out to be handicapped because their anatomic defects will be discovered only later in life in a more advanced state.

Therefore, with routine circumcision we may improve the statistics of UTI in male infants younger than 1 year, but the final outcome may be unfavorable after this arbitrary end point. This fact should also be disclosed to parents when they decide about circumcising their sons.

In Reply—Dr Hopp and Drs Rockney and Caldamone discuss an important aspect of the relationship between UTI, noncircumcision, and anatomic abnormalities of the urinary tract. I did not mean to imply that the presence of a foreskin causes anatomic abnormalities—that seems highly improbable. Rather, I agree that noncircumcision is an additional risk factor that, by provoking UTI, can aid in detecting anatomic abnormalities that are already present. This may be of long-term benefit to the child, as Dr Hopp suggests. However, it is difficult to advocate catching one disease (UTI) to prevent another, albeit a more serious one (possible end-stage renal disease from reflux). Fortunately a safer screening test is being widely used—prenatal ultrasound. More and more congenital urologic abnormalities are being detected by prenatal ultrasound, which may someday render this whole discussion moot.

Breath Hydrogen in Preterm Infants

Sir—I read the report by Cheu et al that supports the claim that breath hydrogen excretion might be useful in the management of the premature neonate at risk for developing necrotizing enterocolitis (NEC). The authors suggest that

it is conceivable that many premature infants undergo a period during which their gut represents an environment conducive

to rapid bacterial growth. During this critical period NEC will develop if bacteria of sufficient virulence proliferate in a quantity sufficient to overcome the bowel's defenses. The degree to which the balance between bacterial growth and bacterial defenses is upset would then determine the severity of the disease, ranging from no disease or feeding intolerance to mild or fulminant NEC.

They do not, however, acknowledge important observations, helping to further substantiate their interpretation.

Stevenson et al² showed that the changes in the number of hydrogen-producing bacteria in the gut contributes to changes in the pulmonary elimination of hydrogen in preterm infants who do not have clinical evidence of carbohydrate intolerance. The change in (Δ) end-tidal hydrogen correlated with the Δ total colony count of Enterobacteriaceae in healthy preterm infants who were in an apparent steady state of nutrition. The intestinal colonization of the preterm infants we studied was characterized by a paucity of anaerobes and biotypes of Enterobacteriaceae. The conspicuous absence of anaerobic bacteria and their eventual appearance in a few infants is very different from the normal pattern of colonization described by Long and Swenson,³ possibly because 83% of the infants we studied had recently received antibiotics. Finally, we concluded that breath hydrogen measurements might provide "a means of detecting changes in gastrointestinal flora and possibly overgrowth with single biotypes of Enterobacteriaceae in preterm infants. This information will permit an evaluation of whether potentially pathogenic Enterobacteriaceae contribute to certain disease states, such as necrotizing enterocolitis and sepsis."²

In a review of the methods and clinical applications of breath hydrogen analysis,⁴ we pointed out that the interpretation of breath hydrogen analysis results in neonates and young infants remains difficult for the reasons below:

1. Although in the adult, a fairly constant fraction of total hydrogen production is excreted in breath, providing a reliable indicator of total colonic production of hydrogen, the fraction of hydrogen excreted in the breath of neonates and young infants cannot be assumed to be the same. We recently reported on simultaneously measured excretion rates of end-tidal hydrogen concentration plus breath

and total body hydrogen (breath hydrogen plus flatus hydrogen).⁵ The fractional breath hydrogen excretion in these infants was 48% (33% to 69%), compared with 21% reported in adults. The correlation coefficient for end-tidal-derived hydrogen excretion and directly measured breath hydrogen excretion rates was .95. We concluded that the proportion of total hydrogen excreted in the breath of neonates is higher compared with adults, suggesting that caution must be exercised when interpreting newborn breath hydrogen measurements using adult norms.

2. Because hydrogen is a byproduct of fermentation by colonic bacteria acting on unabsorbed carbohydrate, its total production is influenced by factors that affect the ability of the flora to act on this carbohydrate. Such factors include (a) the type of bacteria; (b) the number of bacteria; (c) the amount of carbohydrate reaching the colon; (d) the transit time; (e) the colonic pH that is related to the absorption of volatile fatty acids produced in association with fermentation; and (f) the presence of small-bowel bacterial overgrowth.

3. Procedures to ensure the reliability of breath sampling in neonates need to be used. Cheu et al argue that the use of carbon dioxide excretion to standardize hydrogen excretion is a logical strategy for improving the accuracy of hydrogen excretion values. We are in agreement with this conclusion. We also concur that, as minute ventilation increases, the hydrogen concentration can decrease more rapidly than does the carbon dioxide concentration in expired gas. Because one of the major possible confounding factors for a false-negative screening test would be environmental contamination of the sample, we suggest that the use of end-tidal carbon monoxide as an internal standard for reducing the error in end-tidal hydrogen measurements due to contamination of repeated breath samples with nonalveolar gas might also be a useful procedure.⁶ In fact, for individual infants, this correction procedure may reveal more marked short-term fluctuations in true alveolar hydrogen concentration.

In summary, we are grateful to see that breath hydrogen excretion might be useful in the management of the premature neonate at risk for the development of NEC. Its successful application as a screening test, however,

will depend on procedures for sample standardization and for ensuring repeated sampling of individual infants over time. Furthermore, a large multicenter collaborative study is needed to define the true positive and negative predictive accuracies of the breath hydrogen screening test for NEC.

Low-Dose Alternate-Day Corticotropin Therapy in the Treatment of Childhood Seizures

Sir.—Corticotropin was used to treat 17 children with intractable epilepsy other than infantile spasms. Treatment was brief, averaging 5.9 weeks, with 3 to 6 IU/kg per day as the starting dose. Remission of seizures, persisting for a year or more, was achieved in 5 (55.6%) of 8 children with myoclonic/akinetic seizures but in none of the 9 patients with intractable generalized clonic or complex partial seizures (GTC-CPS) ($P < .01$, Fisher's Exact Test). No patient suffered serious side effects.

A short course of low-dose corticotropin therapy appears useful for some children with myoclonic/akinetic seizures but not for patients with intractable GTC-CPS epilepsy.

Corticotropin has been recognized as a valuable anticonvulsant since 1950.¹ Its use, however, has been mainly confined to children with infantile spasms. In 1983, Snead et al² reported that corticotropin completely controlled the

seizures in all 52 patients studied with infantile spasms and in 74% of 64 children with other types of intractable seizures. Their protocol began with 150 U/m² of body surface area daily for 1 week. The dose was then tapered over the subsequent 11 weeks. Significant side effects with high-dose corticotropin therapy have been reported by other authors and include irritability, hypertension, vomiting, gastrointestinal tract bleeding, and peripheral edema.^{2,3}

As corticotropin is very effective in the treatment of infantile spasms, we hypothesized that myoclonic seizures in older children might be more responsive to such therapy than other types of seizures. We studied the effect of a low-dose protocol of corticotropin therapy in 17 children with myoclonic/akinetic seizures or intractable GTC-CPS epilepsy.

Patients and Methods.—In 1983 we standardized our protocol for the use of corticotropin in the treatment of children with seizures. Our typical regimen was a 6-week course, usually starting with 4 to 6 IU/kg per day of corticotropin gel given as a daily intramuscular injection for 1 week. A lower starting dose was used in older children, but the average initial dose was 4.1 IU/kg per day. In the second week corticotropin was given every other day at the same dose as during week 1 and was subsequently tapered to an every-other-day regimen to complete a 6-week course. All patients started to receive treatment as inpatients in the neurology ward of our hospital. Parents were taught to give the injections, and treatment was continued at home. Two children were discharged to the care of their parents within 24 hours of commencing corticotropin therapy.

Follow-up consisted of weekly physical examinations and blood pressure measurements during treatment, usually by the patient's family physician. All children were assessed in our seizure clinic prior to starting therapy and at its completion. All patients have been followed up for at least 3 years after corticotropin therapy and were seen in person in 1988.

We reviewed the records of all children who were treated with a 6-week or shorter course of corticotropin for seizures in our institution between 1983 and 1985. The I. W. K. Hospital for Children, Halifax, Canada, serves as the referral center for all children with epilepsy in the Canadian Maritime Provinces (population, approximately 1.5 million).

The charts were reviewed for seizure type, neurological and developmental status at the onset of treatment, other clinical abnormalities, and age at the onset of seizures and treatment. The electroencephalograms (EEGs) were all interpreted by one of us (P.R.C.). The dose, duration, and efficacy of corticotropin and any side effects were

recorded.

Seizure categories were defined according to the clinical seizure type, with those who had predominantly myoclonic seizures, other than infantile spasms, or akinetic seizures being classified as myoclonic/akinetic. Those with intractable GTC-CPS epilepsy had either generalized clonic or complex partial seizures that had not been controlled by at least four anticonvulsant drugs (mean, 6.5 drugs; range, four to eight drugs). Infantile spasms were not considered.

Among those with intractable GTC-CPS epilepsy, seven had predominantly generalized tonic-clonic seizures while two had mainly complex partial seizures. Two of the children with tonic-clonic seizures also had akinetic seizures and two others also had atypical absence epilepsy. Another child in the GTC-CPS group had gelastic seizures that subsequently resolved spontaneously.

The average age of those with myoclonic seizures (eight patients) was 5.7 years (range, 1.5 to 10.5 years) and of the intractable epilepsy group (nine patients) was 6.4 years (range, 2.5 to 14 years). The average interval between seizure onset and corticotropin treatment was 4.66 years (range, 2 to 13.5 years) for those with intractable GTC-CPS seizures and 2.75 years (range, 1 week to 7.5 years) for those with myoclonic seizures.

The duration of corticotropin treatment for all children with myoclonic/akinetic seizures was 6 weeks. Eight children with intractable GTC-CPS epilepsy were treated for 6 weeks, but one was treated for 4 weeks (average, 5.8 weeks).

The number of seizures was assessed by the parents. As they may not have recognized all episodes, we limited the estimation of response to two categories: *positive* when there was complete seizure control for 6 months or longer and *negative* when there was less than 100% decrease in the seizure frequency or when the response persisted for less than 6 months.

Results were analyzed in the form of a 2 × 2 table, using Fisher's Exact Test.

Results.—In the myoclonic/akinetic group five children (62.5%) had positive responses and three (37.5%) had negative ones. None of the nine with intractable GTC-CPS epilepsy had a positive result ($P < .01$, Fisher's Exact Test).

Among the children who had positive responses, all had a period with no witnessed seizures that lasted from 10 months to 3 years. Two patients continue to be seizure free after 3 years.

Neurological or developmental abnormalities prior to the onset of treatment did not influence the response to therapy. In those with myoclonic seizures one of five was developmentally normal in the group that responded, but all those who had a negative response were developmentally delayed. In the intractable GTC-CPS epilepsy group there were two children who were developmentally normal, although neither responded to corticotropin therapy.

The interval between the commencement of corticotropin therapy and the onset of seizures was similar in both the children who responded and those who did not in the myoclonic epilepsy groups, at 2.75 and 2.83 years, respectively.

The side effects in our patients consisted of stimulus-induced irritability, acne, and a mild cushingoid appearance. Hypertension did not occur, and other serious adverse effects were not observed.

A remarkable improvement in the EEG was seen in two of the five children with positive responses, as detailed below.

Patient Reports.—Patient 1 was delivered at 27 weeks' gestation and suffered an intraventricular hemorrhage with subsequent hydrocephalus, seizures, profound mental retardation, and spastic quadriplegia. He was treated with phenobarbital, but at 17 months of age myoclonic seizures were noted. He was treated with corticotropin for 6 weeks with an initial dose of 5.7 IU/kg per day. The seizures stopped prior to the completion of the course of corticotropin therapy. His EEG was dominated by high-voltage delta background activity with frequent polyspike and wave epileptiform discharges at 2 Hz prior to the start of corticotropin therapy and showed remarkable improvement when repeated 2 weeks following the completion of the course. At 22 months of age he was weaned from phenobarbital therapy. He remained seizure free until 27 months of age when he had a further generalized clonic seizure, which was followed by treatment with diphenylhydantoin. He has remained seizure free at 56 months of age.

Patient 2 was normal until 4 years of age when frequent myoclonic/akinetic seizures began. His EEG showed multifocal spikes but findings of all other investigations were normal. He had two generalized clonic seizures prior to starting corticotropin therapy. The initial dose of corticotropin was 5 IU/kg per day, and the course, which lasted 6 weeks, resulted in a complete resolution of his seizures. Now, at age 6½ years, he is neurologically normal and is free of seizures while receiving no medication.

Patient 3, a 14½-year-old girl, was treated for a medulloblastoma that occurred at 2½ years of age. Her residual deficits include mental retardation, leukoencephalopathy and frequent clonic and complex partial seizures. Multiple anticonvulsant drug failed to control her epilepsy, but at age 1 years she had almost exclusively myoclonic seizures. Despite a trial of valproic acid, she continued to have about 10 seizures per day and, at age 10½ years, she was given a 6 week course of corticotropin therapy (starting dose, 3.75 IU/kg per day). Her seizure stopped within 1 week of commencing corticotropin therapy, and she remained seizure free for 12 months. The EEG before corticotropin therapy was dominated by synchronous spike and slow-wave discharges, but when repeated 1 month later no epileptiform discharges were seen. Her myoclonic seizures returned; a second course of corticotropin therapy was without benefit.

Patient 4 was a developmentally delayed girl with XXX syndrome and epilepsy. Her seizures were predominantly myoclonic, and she was treated with multiple anticonvulsant drugs without success. At 6 years of age she received a 6-week course of corticotropin therapy, which resulted in 1 year without seizures. When her seizures recurred, a second course of corticotropin therapy was given but failed to control her seizures.

Patient 5 was born at 37 weeks' gestation but suffered an intraventricular hemorrhage in the neonatal period with a residual porencephalic cyst and hydrocephalus. When seen at 26 months of age he had a 6-month history of frequent myoclonic seizures (15 to 25 per day). Control was not achieved with valproic acid, and at 30 months of age he was given a 6-week course of corticotropin therapy (starting dose, 3 IU/kg per day). After 2 weeks of therapy his seizures stopped, and 2 months later valproic acid therapy was discontinued. He presented 14 months later with headaches due to a large intracranial tumour that had not been present on previous cranial computed tomographic scans. Following therapy for his tumor, further seizures occurred and he died at 6 years of age.

Comment.—In 1950, Klein and Livingston¹ reported a brief improvement in seizure control in four of six patients treated with corticotropin. The mode of action of corticotropin as an anticonvulsant remains obscure, although there is general agreement that it is beneficial in the treatment of infantile spasms. It is known, however, that dense axonal networks that contain corticotropin are widely distributed in the brain.⁴ It has been speculated that corticotropin may act as a neurotransmitter or neuromodulator that can regulate the number of γ -aminobutyric acid (GABA) receptors in specific brain regions.⁶ In the developing rat brain, corticotropin reduces seizure susceptibility and has no long-term adverse effects on neuronal growth.⁶

The evaluation of corticotropin in the treatment of epilepsy has been complicated by the variability of both the

dosage and duration of treatment in the published studies.⁷ In 1983, Snead et al⁸ found that 74% of 64 children with intractable epilepsy other than infantile spasms had complete seizure control following treatment with corticotropin. Long-term control of seizures was obtained in only 56% (nine patients) with myoclonic seizures other than infantile spasms and in 33.3% (six patients) with other types of intractable seizures.

We separated our patients with myoclonic seizures from those with other types of seizures as we postulated that infantile spasms and therefore possibly other myoclonic seizures are most responsive to corticotropin.

We found that five patients (62.5%) with predominantly myoclonic seizures had prolonged improvement in their seizure control, all becoming essentially seizure free for at least 1 year. The remaining three children (37.5%) had no change in their seizure frequency. No patient with intractable GTC-CPS epilepsy benefited from corticotropin therapy. This difference in response was statistically significant ($P < .01$).

Our results are more consistent with the data reported by Snead et al⁸ in a subsequent study. In this second study, they found that eight of nine patients with severe mixed seizure disorders initially did well but that all except one had a recurrence of seizures as the corticotropin dosage was tapered.

The absence of serious side effects in our patients may have been the result of our regimen of alternate day medication after the first week of treatment. This protocol is also more acceptable to parents and is less expensive than most other corticotropin regimens.

We conclude that corticotropin at an initial dose of 2 to 6 IU/kg per day for 1 week and then alternate-day treatment in decreasing doses for a total 6-week course is a useful and safe treatment for older children with myoclonic epilepsy. We were unable to demonstrate

the value of corticotropin in treating other types of intractable GTC-CPS epilepsy.

NEW FROM McNEIL

**Pedia
Profen™**

Ibuprofen Suspension 100 mg/5 ml

A new therapeutic alternative for fever

Antipyretic efficacy

In children with temperatures greater than 102.5°F, ibuprofen 10 mg/kg is more effective than ibuprofen 5 mg/kg or acetaminophen 10 mg/kg.¹

PediaProfen is indicated for the reduction of fever in children 6 months and older.

Longer duration of action than acetaminophen for fever^{1,2}

Ibuprofen 10 mg/kg provides up to 8-hour relief. That means fewer interruptions in the family's work, school, or sleep schedules.

Safety profile*

See brief summary of Prescribing Information. Significant adverse effects are reported with NSAIDs. Serious as well as minor side effects can occur with long-term use of high-dose ibuprofen. In clinical studies with over 400 pediatric patients, no significant adverse reactions were reported during short-term therapy for fever.²

Pleasant-tasting

Designed for compliance; well liked by patients in clinical studies.²

References:

Introducing Rx

Pedia Profen™

Ibuprofen Suspension
100 mg/5 ml

New **PediaProfen**TM

Ibuprofen Suspension 100 mg/5 ml

The following is a brief summary only. Before prescribing, see complete prescribing information in **PediaProfen** labeling.

INDICATIONS AND USAGE: **PediaProfen** is indicated for the reduction of fever in patients aged 6 months and older, and for the relief of mild-to-moderate pain in patients aged 12 years and older.

CLINICAL PHARMACOLOGY: Controlled clinical trials comparing doses of 5 and 10 mg/kg ibuprofen and 10-15 mg/kg of acetaminophen have been conducted in children 6 months to 12 years of age with fever primarily due to viral illnesses. In these studies there were no differences between treatments in fever reduction for the first hour and maximum fever reduction occurred between 2 and 4 hours. Response after 1 hour was dependent on both the level of temperature elevation as well as the treatment. In children with baseline temperatures at or below 102.5°F both ibuprofen doses and acetaminophen were equally effective in their maximum effect. In those children with temperatures above 102.5°F, the ibuprofen 10 mg/kg dose was more effective. By 6 hours children treated with ibuprofen 5 mg/kg tended to have recurrence of fever, whereas children treated with ibuprofen 10 mg/kg still had significant fever reduction at 8 hours. In control groups treated with 10 mg/kg acetaminophen, fever reduction resembled that seen in children treated with 5 mg/kg of ibuprofen, with the exception that temperature elevation tended to return 1-2 hours earlier.

CONTRAINDICATIONS: **PediaProfen** should not be used in patients who have previously exhibited hypersensitivity to ibuprofen, or in individuals with all or part of the syndrome of nasal polyps, angioedema and bronchospastic reactivity to aspirin or other nonsteroidal anti-inflammatory agents. Anaphylactoid reactions have occurred in such patients.

WARNINGS: Risk of GI Ulceration, Bleeding and Perforation with NSAID Therapy. Serious gastrointestinal toxicity such as bleeding, ulceration, and perforation, can occur at any time, with or without warning symptoms, in patients treated chronically with NSAID therapy. Although minor upper gastrointestinal problems, such as dyspepsia, are common, usually developing early in therapy, physicians should remain alert for ulceration and bleeding in patients treated chronically with NSAIDs even in the absence of previous GI tract symptoms. In patients observed in clinical trials of several months to two years duration, symptomatic upper GI ulcers, gross bleeding or perforation appear to occur in approximately 1% of patients treated for 3-6 months, and in about 2-4% of patients treated for one year. Physicians should inform patients about the signs and/or symptoms of serious GI toxicity and what steps to take if they occur.

Studies to date have not identified any subset of patients not at risk of developing peptic ulceration and bleeding. Except for a prior history of serious GI events and other risk factors known to be associated with peptic ulcer disease, such as alcoholism, smoking, etc., no risk factors (e.g., age, sex) have been associated with increased risk. Elderly or debilitated patients seem to tolerate ulceration or bleeding less well than other individuals and most spontaneous reports of fatal GI events are in this population. Studies to date are inconclusive concerning the relative risk of various NSAIDs in causing such reactions. High doses of any NSAID probably carry a greater risk of these reactions, although controlled clinical trials showing this do not exist in most cases. In considering the use of relatively large doses (within the recommended dosage range), sufficient benefit should be anticipated to offset the potential increased risk of GI toxicity.

PRECAUTIONS: General: Blurred and/or diminished vision, scotomata, and/or changes in color vision have been reported. If a patient develops such complaints while receiving **PediaProfen**, the drug should be discontinued and the patient should have an ophthalmologic examination which includes central visual fields and color vision testing.

Fluid retention and edema have been reported in association with ibuprofen, therefore, the drug should be used with caution in patients with a history of cardiac decompensation or hypertension.

PediaProfen, like other nonsteroidal anti-inflammatory agents, can inhibit platelet aggregation, but the effect is quantitatively less and of shorter duration than that seen with aspirin. Ibuprofen has been shown to prolong bleeding time (but within the normal range), in normal subjects. Because this prolonged bleeding effect may be exaggerated in patients with underlying

hemostatic defects, **PediaProfen** should be used with caution in persons with intrinsic coagulation defects and those on anticoagulant therapy.

Patients on **PediaProfen** should report to their physician signs or symptoms of gastrointestinal ulceration or bleeding, blurred vision or other eye symptoms, skin rash, weight gain, or edema.

In order to avoid exacerbation of disease of adrenal insufficiency, patients who have been on prolonged corticosteroid therapy should have their therapy tapered slowly rather than discontinued abruptly when ibuprofen is added to the treatment program.

The antipyretic and anti-inflammatory activity of **PediaProfen** may reduce fever and inflammation, thus diminishing their utility as diagnostic signs in detecting complications of presumed noninfectious, noninflammatory painful conditions.

Since ibuprofen is eliminated primarily by the kidneys, patients with significantly impaired renal function should be closely monitored and a reduction in dosage should be anticipated to avoid drug accumulation. Prospective studies on the safety of ibuprofen in patients with chronic renal failure have not been conducted.

Safety and efficacy of **PediaProfen** in children below the age of 6 months has not been established.

Pregnancy: Reproductive studies conducted in rats and rabbits at doses somewhat less than the maximal clinical dose did not demonstrate evidence of developmental abnormalities. However, animal reproduction studies are not always predictive of human response. As there are no adequate and well-controlled studies in pregnant women, this drug should be used during pregnancy only if clearly needed. Because of the known effects of nonsteroidal anti-inflammatory drugs on the fetal cardiovascular system (closure of ductus arteriosus), use during late pregnancy should be avoided. As with other drugs known to inhibit prostaglandin synthesis, an increased incidence of dystocia and delayed parturition occurs in rats. Administration of **PediaProfen** is not recommended during pregnancy.

ADVERSE REACTIONS: The most frequent type of adverse reaction occurring with ibuprofen is gastrointestinal. In controlled clinical trials, the percentage of adult patients reporting one or more gastrointestinal complaints ranged from 4% to 16%.

Adverse reactions occurring in 3% to 9% of patients treated with ibuprofen: nausea, epigastric pain, heartburn, dizziness, rash. *Adverse reactions occurring in 1% to 3% of patients:* diarrhea, abdominal distress, nausea and vomiting, indigestion, constipation, abdominal cramps or pain, fullness of GI tract, headache, nervousness, pruritus, tinnitus, decreased appetite, edema, fluid retention (generally responds promptly to drug discontinuation). Still other reactions (less than 1 in 100) have been reported, and are detailed in the full summary of prescribing information.

DOSAGE AND ADMINISTRATION: Shake well prior to administration.

Fever Reduction in Children 6 months to 12 years of age Dosage should be adjusted on the basis of the initial temperature level (See CLINICAL PHARMACOLOGY for a description of the controlled clinical trial results). The recommended dose is 5 mg/kg if the baseline temperature is less than 102.5°F or 10 mg/kg if the baseline temperature is greater than 102.5°F. The duration of fever reduction is generally 6-8 hours and is longer with the higher dose. The recommended maximum daily dose is 40 mg/kg.

Mild to moderate pain: 400 mg every 4 to 6 hours as necessary for the relief of pain in adults.

In controlled analgesic clinical trials, doses of ibuprofen greater than 400 mg were no more effective than 400 mg dose.

HOW SUPPLIED: **PediaProfen** Ibuprofen Suspension 100 mg/5 ml (teaspoon)—

orange, berry-vanilla flavored

Bottles of 4 oz (120 ml)..... NDC 0045-0469-1

Bottles of 16 oz (480 ml)..... NDC 0045-0469-2

SHAKE WELL BEFORE USING. Store at room temperature.

Caution: Federal law prohibits dispensing without prescription.

Growth Retardation

Impaired Height Velocity

Growth results from an increase in cell number and/or cell size. Availability of basic building materials (nutrition) and the ability to utilize them (normal organ systems) influence growth. Genes, the blueprints for the organ systems, determine growth efficiency.^{1,2} Clinical assessment of growth is based on serial measurements of height and weight over time. Change occurring in relation to time is a velocity. In evaluating growth velocity, it should be noted that there may be no measurable growth during a single 3-month period in a normal child.³

See also pp 1282, 1284, and 1287.

Subsequent to birth, height and weight velocity decelerate.^{4,5} Height velocity decelerates from 25 cm/y to a minimal basal velocity of 5 cm/y by the third year of life. Programmed genetic variation as to what basal velocity is achieved, and how rapidly the deceleration occurs for a normal population, is graphically indicated as the percentile rankings on a growth chart.

Individuals who are slow in somatic growth are less growth efficient than the general population and achieve the minimal basal height velocity more rapidly than the general population.⁶ Their heights, when plotted on a growth chart, will be below the third percentile. But, because they are growing at the minimal basal height velocity, a graphic depiction of their height will parallel that of the general population.⁶

Basal height velocity is facilitated by thyroid and growth hormone. Following the onset of puberty, height velocity is accelerated by the sex steroids, androgens and estrogens. Because of their effect on epiphyseal fusion (bone age), the sex steroids

ultimately stop height velocity, and adult height is achieved.

Height below the third percentile is defined as "short stature." Adults with heights that are less than the third percentile, who were slow in somatic growth during childhood, and whose family members have similar adult heights are referred to as having "familial short stature." During childhood they have bone ages and chronological ages that are comparable. They also have the initiation of puberty by the mean chronological age expected for its onset.

Individuals who were slow in somatic growth during childhood, and whose adult height is greater than the third percentile (usually the fifth percentile or more), are referred to as having "constitutional short stature." During childhood their bone age is less than their chronological age. They also have the initiation of puberty at a later age than the mean chronological age expected for its onset.

Short stature is a disadvantage in our society.⁷ In the context of height, bigger is better. A person whose accomplishments are remarkable is spoken of as a "person of stature." The appearance of the short child invites "babying." This contrasts with the favored position of the tall child whose innate abilities are presumed to develop more rapidly than those of the short child. Understandably, since the world of the adult is no less biased, a parent would be most anxious to treat a short child. This would be particularly true for a parent similarly stigmatized.

Because of the commercial availability of biosynthetic growth hormone (GH), medical indications and cost are the only limiting factors for prescribing GH. Physicians are presented with two fundamental questions. First, how

can we recognize (through testing and/or trials of GH therapy) the short child who will benefit from GH treatment? Second, ethically, should a child's limited genetic potential for height be augmented by treatment with GH?

Overlapping results make testing for GH secretion alone unable to identify the individual who is GH deficient. This is true whether the evaluation of GH secretion is direct (overnight secretion,^{8,9} 24-hour integrated secretion,¹⁰ or provocative stimuli testing¹¹⁻¹³) or indirect (somatomedin/insulinlike growth factor 1¹⁴). Only when the testing procedure or procedures are combined with a height velocity that is less than the minimal basal height velocity of 5 cm/y can we identify the individual who is GH deficient. It is, therefore, not possible to determine whether the individual who is growing at a basal height velocity of 5 cm/y is growing at an optimum rate for that individual.

A growth response to treatment with GH has been demonstrated in two categories of subjects: those with impaired height velocity and abnormal results of GH testing (classic growth hormone deficiency¹⁵ and GH neurosecretory dysfunction¹⁶), and those with impaired height velocity and normal results of GH testing (bioinactive growth hormone,^{17,18} "normal variant" short stature,^{14,19-23} Turner's syndrome,²⁴⁻²⁶ Down syndrome,²⁷ intrauterine growth retardation,^{28,29} and, as reported in this issue of *AJDC*,³⁰ subjects with microcephaly). All of the patients in the first category responded to GH treatment. Only some of the patients in the second category responded to GH treatment. By and large, the responders in the second category had delayed bone age, height velocity less than 4 to 5 cm/y, and height less than the first percentile.

Whether it is appropriate to augment limited genetic potential for height with GH treatment should be examined in relation to the possibility of adverse consequences (risks) of this action. No medical treatment is entirely risk free. Recently, adverse or potentially adverse consequences have been recognized in GH-deficient patients treated with GH. Creutzfeldt-Jakob disease, resulting from treatment with GH derived from pituitary glands, was recognized in 1985 and eliminated by utilizing only biosynthetic GH.^{31,32} Suppression of immune function was reported in 1986.³³ The depression of immune function was not associated with ill effects. An increase in the risk of leukemia was reported in 1988.³⁴ From current estimates, the increased risk to an individual GH-treated patient is probably twice the natural risk. Assuming a 10-year GH treatment, this would mean 1 chance in 2400 (0.042%).

The foregoing reports serve to reinforce the caution that GH should never be used indiscriminately. Since GH is essential for growth and development, it would be inappropriate to withhold GH treatment from GH-deficient subjects. Indiscriminate use of GH therapy to treat short children who are not GH deficient is strongly discouraged.

To assess the proper place for GH therapy in the treatment of the short child, we need special knowledge of childhood diseases, growth, and endocrinology. A decision to treat the short child is best left to the pediatric endocrinologist.

Child Passenger Safety

Past, Present, and Future

All clinical research must be interpreted in its historical context. For studies of motor vehicle occupants, that context has been changing particularly quickly.

Past

Once upon a time, not so very long ago, children were always loose when riding in cars. It was not until 1968 that seat belts were required in cars at all.¹ The very first child passenger restraint law for preschool children went into effect in Tennessee in 1978.

See also p 1317.

The 50th state passed its law in 1984. Surveys by the National Highway Traffic Safety Administration indicated that in 1979, 15% of child passengers 0 to 4 years old were restrained compared with 49% in 1984.²

Present

The expectation that children should be protected when they ride in cars, a fairly new one for our society, is already sufficiently strong that car safety seat use among young children now approaches that of immunizations: in 1989, National Highway Traffic Safety Administration surveys showed 82.5% restraint use by 0- to 4-year-olds in shopping center parking lots.² Thus, the good news is that we have come a long way toward safe travel for our children.

The bad news is that we still have a way to go before we can say that US children are riding safely on every ride they take. There are deficiencies in several areas.

Though children under 5 years old are increasingly riding restrained, the rates of *proper* restraint remain frustratingly low. Thus, although parents now recognize the importance of adequate restraint, they are not success-

fully providing it. Furthermore, restraint use, and, more particularly, restraint misuse, is becoming a factor in injury patterns.³

Children who are beyond the age of child passenger restraint laws are apparently also beyond the full reach of the society's expectation of restraint. National Highway Traffic Safety Administration estimates of seat belt use in children ages 5 to 13 years were 15% in 1984 and 39% in 1988. For 13- to 19-year-old passengers it was even worse: 7% in 1984 and 24% in 1988. This is a tragedy, because passengers who travel restrained have a markedly reduced risk of serious head injury, and thus have a reduced risk of resulting death or permanent neurologic handicap. The National Highway Traffic Safety Administration has estimated that "among front-seat passenger vehicle occupants over 4 years old, safety belts saved about 4,500 lives in 1988... [and] prevented about 119,000 moderate to critical injuries."⁴

Now Agran et al⁵ have demonstrated that seat belts do not work as well as we had hoped for older children: they prevent ejection, but serious injuries still occur, especially with lateral crash impacts. Others have shown that as seat belt use has risen, features of belt restraint are becoming factors in child occupant injury patterns.³

Among older adolescents and young adults, the problem remains the "old" one, nonuse of seat belts.

Some vehicles are exempt from some of the structural safety requirements that passenger sedans must meet (eg, concerning roof strength and passive restraints).

Future

Much work remains before the goal of universal safe transport of child and adolescent motor vehicle occupants is realized. Our work is cut out for us,

though in some areas the specific steps we need to take remain unclear.

Universal proper use of child safety seats will require increasing simplicity and uniformity of safety seats and seat belts (they are now often incompatible). Strong and specific federal standards make sense here.

Gaps in child restraint laws need to be closed to assure that *every* child is covered by the expectation of safe transport. In addition to raising the upper age limit to encompass all children, specific exemptions in various states should be eliminated (eg, exemptions for nonresidents or passengers not in their own family's car). Enforcement, with the goal of universal compliance rather than punishment, is essential.

Seat belt systems should optimally restrain people of all sizes who are too big for current child safety seats. In addition to lap belts, shoulder harnesses—preferably with adjustable anchor points for individuals of varying heights—should be required in *all* seating positions. Booster seats can help to properly position the shoulder belt for younger children. Other types of safety seats may be needed for older children.

Gaps need to be closed in the regulations that mandate which vehicles meet which safety standards. Certainly, vans, mini vans, and other light trucks that are often used as family cars must be designed to protect their occupants as well as sedans do.

The study by Agran et al⁵ suggests that new vehicle standards may be needed to enable vehicles to resist crash intrusions into the passenger compartment and to prevent passenger head impact with front seats.

Means must be found to increase the chances that teenagers will survive our car culture. Steps that are likely to help include the following: air

bags and other nondetachable passive restraints (now finally on the horizon); raising a generation of seat-belted children (facilitated by the steps outlined above for school-aged children); steps to decrease the alcohol indulgence of driving age teens (eg, curfews, raised ages for drinking and driving, and alcohol-free party alternatives); and strict and visible enforcement of seat belt laws for new drivers (ages 16 to 22 years are the years of highest crash risk), with specific and stringent penalties for non-use.

Adequate equipment and care protocols are needed to safely transport premature infants and medically fragile children of all ages. These are beginning to be developed.

Financial obstacles to acquiring child safety seats should be removed as part of the current effort to remove all access obstacles to child health care.

The study by Agran et al⁵ shows that seat belts are good but not yet good enough. Similarly, the effort toward safety for children in cars has come a long way but not far enough.

The American Academy of Pediatrics' "Every Ride a Safe Ride" program is available to provide support to pediatricians and others as we work to both maintain our gains and move ahead.

While we work on the steps outlined above, parents should be urged most strongly to use the available restraint systems as best they can: they are the best we have, and they are a big improvement over that time, not so long ago, when children were always dangerously loose in cars.

Morbidity and Mortality Report
Centers for Disease Control, Atlanta

Measles Outbreak—Chicago, 1989

AS OF AUGUST 23, 1989, 1123 confirmed cases of measles have been reported to the Chicago Department of Health. Information is available for 1019 (91%) of these cases; 799 (78%) have occurred in preschool-aged children (less than 5 years old), including 340 (33%) children less than 16 months of age (i.e., too young for routine immunization). Blacks and Hispanics have accounted for 955 (94%) of the cases. Four measles-associated fatalities have been reported.

Outbreak-control activities have included intensified surveillance and lowering of the recommended age for measles vaccination to 6 months during the outbreak, with revaccination at age 15 months for children vaccinated before the first birthday. Single-antigen measles vaccine is being used for children before the first birthday, and measles-mumps-rubella vaccine (MMR) is administered to older children. Seven new vaccination clinics

have been established and have administered approximately 21,000 doses of vaccine; door-to-door vaccination teams in high-risk communities have administered an additional 2000 doses of vaccine. Hospital emergency department vaccination clinics have been set up in four locations.

Reported by: RM Krieg, PhD, RW Biek, MD, CR Catania, JW Masterson, MPH, Chicago Dept of Health; R March, Immunization Program, RJ Martin, DVM, Div of Infectious Diseases, Illinois Dept of Public Health. Div of Immunization, Center for Prevention Svcs, CDC. (MMWR vol 38 No. 34).

CDC Editorial Note: This outbreak is similar to others among inner-city populations in the United States in that it involves primarily unvaccinated black and Hispanic preschool-aged children.¹⁻³ The Chicago Department of Health has implemented aggressive outbreak strategies directed toward reaching the highest-risk group, i.e.,

unvaccinated preschool-aged children. Such children are also likely to be a reservoir for transmitting virus to other age groups. As part of the extensive outbreak-control efforts, children are being vaccinated in emergency departments. Provision of vaccine to inner-city children who use these facilities for their primary source of health care should help to increase vaccination levels in patients who receive sporadic health care and may reduce the transmission of measles in emergency department settings.

Prevalence of Drug Use among Applicants for Military Service—United States, June-December 1988

SINCE JUNE 1988, the U.S. Department of Defense has screened all applicants for military service (including the U.S. Coast Guard) for evidence of marijuana and/or cocaine use as mandated by the National Defense Authorization Act of 1988. Applicants confirmed as cocaine-positive are not eligible for military service for 1 year from the date of screening; those confirmed as marijuana-positive are not eligible for military service for 6 months from the date of screening. Persons who tested positive twice for either drug are not eligible for military

service for 2 years from the date of the second test.¹

A pilot study was conducted during March and April 1988 to determine the prevalence of marijuana and/or cocaine use among applicants before the initiation of the program in June. For the pilot study, applicants were not informed about the drug test. However, because personal identifiers were not recorded, results could not be linked to individual applicants. Urine specimens collected as part of the induction physical examination were sent to three of nine military

laboratories and screened by radioimmunoassay (Roche Diagnostic Systems Abuscreen Test Kits[®]) for marijuana and cocaine. Six thousand (42%) urine specimens were selected at random from approximately 14,200 obtained from 12 of 70 Military Entrance Processing Stations. Four hundred thirty-seven (7.3%) and 108 (1.8%) screened positive for marijuana or cocaine, respectively, or their metabo-

¹Use of trade names is for identification only and does not imply endorsement by the Public Health Service or the U.S. Department of Health and Human Services.

lites, and 42 (0.7%) were positive for both marijuana and cocaine (Office of the Army Surgeon General, unpublished data). Although positive specimens were not confirmed, data from military drug-screening laboratories indicate that at least 85% of cocaine and 90% of marijuana users would have been confirmed positive (Office of the Assistant Secretary of Defense for Health Affairs, unpublished data).

From June through December 1988, 322,256 applicants were informed that a urine specimen would be collected for drug screening at the induction physical examination. Positive specimens were confirmed by gas chromatography/mass spectrometry.** The Headquarters for the U.S. Military Entrance Processing Command² provided demographic data.

Of all applicants tested, 3.5% were positive for marijuana and/or cocaine. Men were 2.6 times more likely than women (3.9%, compared with 1.5%,

**In the initial screening, the following levels indicated positivity: greater than or equal to 100 ng/mL for marijuana and greater than or equal to 300 ng/mL for cocaine. Positivity was confirmed at greater than or equal to 15 ng/mL for marijuana and greater than or equal to 150 ng/mL for cocaine.

respectively) to be positive for marijuana and/or cocaine. Blacks were 1.9 times and Hispanics 1.4 times more likely than whites to test positive (5.6% for blacks and 4.0% for Hispanics, compared with 2.9% for whites). The percentage positive for either drug increased with age (1.3% in 17- and 18-year-olds, compared with 5.3% in greater than or equal to 26-year-olds). Geographic variation for cocaine and/or marijuana ranged from 2.5% in the West North Central to 5.3% in the Mid-Atlantic states. The percentage screened positive for marijuana and/or cocaine varied inversely with education level: the highest prevalence was in applicants who had not graduated from high school (7.5%) and the lowest in those educated beyond a 4-year college degree (0.7%).

Div of Environmental Hazards and Health Effects, Center for Environmental Health and Injury Control, CDC (MMWR vol 38, No. 33).

CDC Editorial Note: This report summarizes the findings of the largest

nonrandom drug testing program in the United States and characterizes evidence of drug use by age, race, and sex in a defined population. Applicants for U.S. military service are a geographically diverse sample of young persons. Extrapolation of marijuana and/or cocaine use in this group to the U.S. population may not be reliable because of social and demographic differences of military applicants in the same age groups. Men and racial and ethnic minorities are overrepresented among applicants.

The decrease in percentage of positives among applicants from the pilot study to the systematic screening program indicates that notifying applicants of the drug-testing program may deter continued use, prompt users to withdraw from the application process, or discourage application for military service.

First 100,000 Cases of Acquired Immunodeficiency Syndrome—United States

IN JUNE 1981, the first cases of the illness now known as acquired immunodeficiency syndrome (AIDS) were reported from Los Angeles in five young homosexual men diagnosed with *Pneumocystis carinii* pneumonia and other opportunistic infections.¹ Since then, state and territorial health departments have reported greater than 100,000 cases of AIDS and greater than 59,000 AIDS-related deaths to CDC. AIDS is now a major cause of morbidity and mortality in children and young adults in the United States, ranking 15th among leading causes of death in 1988² and seventh among estimated years of potential life lost before age 65 in 1987.³ The first 50,000 cases of AIDS were reported to CDC from 1981 to 1987; the second 50,000 were reported between December 1987 and July 1989.

Although homosexual/bisexual men still account for most reported AIDS cases, intravenous-drug users (IVDUs), their sex partners, and their children represent an increasing proportion of all cases. Of AIDS cases reported before 1985, 63% were homosexual/bisexual men with no history of IV-drug use, 18% were female or heterosexual male IVDUs, and 2% were sex partners or children of IVDUs or their sex partners. In contrast, of the AIDS cases reported in the first 6 months of 1989, 56% were homosexual/bisexual men with no history of IV-drug use, 23% were female or heterosexual male IVDUs, and 4% were sex partners or children of IVDUs or their sex partners. The proportion of AIDS cases among women has also increased from 7% of cases reported before 1985 to 11% of

cases reported in the first 6 months of 1989. Blacks and Hispanics continue to be disproportionately represented among all persons with AIDS and particularly among IVDUs with AIDS. Although most AIDS cases are reported from large metropolitan areas, an increasing proportion are being reported from smaller cities and rural areas. Metropolitan statistical areas with populations less than or equal to 500,000 reported 10% of a U.S. cases before 1985, compared with 19% in 1988.

Reported by: AIDS Program, Center for Infectious Diseases, CDC. (MMWR vol. 38, No. 32)

CDC Editorial Note: The 100,000 AIDS cases reported in the United States as of July 1989 represent the minimum number of persons with s

vere human immunodeficiency virus (HIV)-related disease. Because of the combination of underdiagnosis and underreporting of AIDS cases and severe manifestations of HIV infection that do not meet the CDC AIDS surveillance case definition, reported AIDS cases underestimate the number of persons severely affected by HIV since 1981. The completeness of diagnosis and reporting of AIDS cases varies by geographic region and patient population; however, mortality studies suggest that 70%-90% of HIV-related deaths are identified through national surveillance of AIDS.⁴

The number of AIDS cases are one indication of the larger epidemic of HIV infection. An estimated 1-1.5 million persons are infected with HIV in the United States,⁵ with recent seroprevalence studies suggesting that the actual number is closer to the lower end of this range.⁶ A cohort study of homosexual/bisexual men in San Francisco suggests that 54% of infected persons will develop AIDS within 10 years of infection⁷ and that up to 99% will eventually develop AIDS.⁸ There-

fore, the number of persons with AIDS and other severe manifestations of HIV infection will continue to increase.

AIDS is reportable in all 50 states, the District of Columbia, and U.S. territories. AIDS surveillance has been crucial in identifying characteristics of persons at risk for the disease and modes of transmission and remains extremely important in monitoring trends in severe HIV-related disease, projecting future numbers of AIDS cases and HIV-infected persons, and targeting resources for prevention and treatment efforts. Because persons with AIDS require a broad range of medical services, documentation of these cases is also important in determining current and future health-care needs and costs. AIDS surveillance data together with information from the HIV family of surveys⁶ and HIV infection reporting⁹ are important components of public health programs directed toward controlling HIV infection and assist in providing the most accurate picture of the HIV epidemic in the United States.

Alupent[®] Syrup

(metaproterenol sulfate)

Bronchodilator

Tablets	Inhalation Aerosol	Syrup	Inhalation Solution	Inhalation Solution
10 and 20 mg	10 mL	10 mg/5 mL	5%	Unit-dose Vials 0.4% and 0.6%

Brief Summary of Prescribing Information

CONTRAINDICATIONS Use in patients with cardiac arrhythmias associated with tachycardia is contraindicated.

Although rare, immediate hypersensitivity reactions can occur. Therefore, Alupent[®] (metaproterenol sulfate USP) is contraindicated in patients with a history of hypersensitivity to any of its components.

WARNINGS Excessive use of adrenergic aerosols is potentially dangerous. Fatalities have been reported following excessive use of Alupent[®] (metaproterenol sulfate USP) as with other sympathomimetic inhalation preparations, and the exact cause is unknown. Cardiac arrest was noted in several cases.

Alupent, like other beta adrenergic agonists, can produce a significant cardiovascular effect in some patients, as measured by pulse rate, blood pressure, symptoms, and/or ECG changes. As with other beta adrenergic aerosols, Alupent can produce paradoxical bronchospasm (which can be life threatening). If it occurs, the preparation should be discontinued immediately and alternative therapy instituted.

Alupent[®] (metaproterenol sulfate USP) should not be used more often than prescribed. Patients should be advised to contact their physician in the event that they do not respond to their usual dose of a sympathomimetic amine aerosol.

PRECAUTIONS General: Extreme care must be exercised with respect to the administration of additional sympathomimetic agents.

Since metaproterenol is a sympathomimetic amine, it should be used with caution in patients with cardiovascular disorders, including ischemic heart disease, hypertension or cardiac arrhythmias, in patients with hyperthyroidism or diabetes mellitus, and in patients who are unusually responsive to sympathomimetic amines or who have convulsive disorders. Significant changes in systolic and diastolic blood pressure could be expected to occur in some patients after use of any beta adrenergic bronchodilator.

Information for Patients: Extreme care must be exercised with respect to the administration of additional sympathomimetic agents. A sufficient interval of time should elapse prior to administration of another sympathomimetic agent.

Drug Interactions: Other beta adrenergic aerosol bronchodilators should not be used concomitantly with Alupent because they may have additive effects. Beta adrenergic agonists should be administered with caution to patients being treated with monoamine oxidase inhibitors or tricyclic antidepressants, since the action of beta adrenergic agonists on the vascular system may be potentiated.

Carcinogenesis/Mutagenesis/Impairment of Fertility: In an 18-month study in mice, Alupent produced an increase in benign ovarian tumors in females at doses corresponding to 320 and 640 times the maximum recommended dose (based on a 50 kg individual). In a two-year study in rats, a non-significant incidence of benign leiomyomata of the mesovarium was noted at 640 times the maximum recommended dose. The relevance of these findings to man is not known. Mutagenic studies with Alupent have not been conducted. Reproduction studies in rats revealed no evidence of impaired fertility.

Pregnancy Teratogenic Effects: Pregnancy Category C: Alupent[®] (metaproterenol sulfate USP) has been shown to be teratogenic and embryotoxic in rabbits when given orally in doses 620 times the human inhalation dose and 62 times the human oral dose. There are no adequate and well-controlled studies in pregnant women. Alupent should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Oral reproduction studies in mice, rats and rabbits showed no teratogenic or embryocidal effects at 50 mg/kg, corresponding to 310 times the human inhalation dose and 31 times the human oral dose. Teratogenic effects in the rabbit included skeletal abnormalities and hydrocephalus with bone separation.

Nursing Mothers: It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Alupent[®] (metaproterenol sulfate USP) is administered to a nursing woman.

Pediatric Use Consult package insert for age limit.

ADVERSE REACTIONS Adverse reactions are similar to those noted with other sympathomimetic agents. Adverse reactions such as tachycardia, hypertension, palpitations, nervousness, tremor, nausea and vomiting have been reported.

The most frequent adverse reaction to Alupent[®] (metaproterenol sulfate USP) administered by metered-dose inhaler among 251 patients in 90-day controlled clinical trials was nervousness. This was reported in 6.8% of patients. Less frequent adverse experiences, occurring in 1-4% of patients were headache, dizziness, palpitations, gastrointestinal distress, tremor, throat irritation, nausea, vomiting, cough and asthma exacerbation. Tachycardia occurred in less than 1% of patients.

HOW SUPPLIED Inhalation Aerosol: Each Alupent[®] Inhalation Aerosol contains 150 mg of metaproterenol sulfate as a micronized powder in inert propellants. Each metered dose delivers through the mouthpiece 0.65 mg metaproterenol sulfate (each mL contains 15 mg). Alupent Inhalation Aerosol with Mouthpiece (NDC 0597-0070-17), net contents 14g (10mL), equipped with blue protective cap. Alupent Inhalation Aerosol Refill (NDC 0597-0070-18), net contents 14g (10 mL).

Store between 59°F (15°C) and 77°F (25°C). Avoid excessive humidity.

Inhalation Solution: Alupent Inhalation Solution is supplied as a 5% solution in bottles of 10 mL or 30 mL with accompanying calibrated dropper. Store below 77°F (25°C). Protect from light. Do not use the solution if it is brown or has a precipitate.

Alupent Inhalation Solution Unit-dose Vial is supplied as a 0.4% or 0.6% clear colorless or nearly colorless solution containing 2.5 mL, with 25 vials per box. Store below 77°F (25°C). Protect from light. Do not use the solution if it is brown or has a precipitate.

Syrup: Alupent is available as a cherry-flavored syrup, 10 mg per teaspoonful (5 mL), in 16 fl. oz. bottles. Store below 86°F (30°C). Protect from light.

Tablets: Alupent is supplied in two dosage strengths as scored, round white tablets in bottles of 100. Tablets of 10 mg coded BI/74. Tablets of 20 mg coded BI/72.

Storage for bottles: Store below 86°F (30°C). Protect from light.

Storage for blister samples. Store below 77°F (25°C). Protect from light.

Consult package insert before prescribing.

Book Review

Linear Growth Retardation in Less Developed Countries, edited by J. C. Waterlow, 313 pp, \$40, New York, NY, Raven Press, 1988.

This book is a record of the proceedings of the 14th Nestle's Nutrition Workshop held in Thailand in March of 1986. It is a series of reports and transcripts of the discussions provoked by each presentation. The list of participants is formidable and includes leading experts in linear growth velocity and experts in the circular relationship between poverty, malnutrition, and growth. Presenters included individuals from countries in the developed and developing world.

The workshop recognized the increased frequency of stunting in the less developed parts of the world. The prevalence of stunting can be used as an index of the poverty level in a given region or country. Although this was an important underlying theme of the proceedings, participants emphasized the biologic determinants and the physical handicaps associated with stunting. The discussions following each presentation were as open and interesting as the reports; they indicate the present state of our knowledge and suggest a multitude of projects to be undertaken that would increase our understanding of the process of stunting and the sequelae of short stature.

J. C. Waterlow opened the volume with a chapter titled "Natural History of Stunting." This is followed by chapters on epidemiology, the best time increments to monitor length, and the relationship between poverty and stature. Three chapters discuss the relative influence the intrauterine environment, genetic endowment, and hormones exert on growth. The role that calcium, zinc, and protein play in determining growth velocity is the subject of the next two chapters. David Narborro from Liverpool, England, wrote a very interesting chapter on the role of infection in growth retardation. The risk of morbidity in the stunted child is presented by Andrew Tomkins from London, England, and W. Van Lerberghe from Belgium discussed the effect retarded linear growth has on mortality. Marta Colombo from Chile presented data on the relationship between mental development and stunting. G. B. Spurr from Wisconsin wrote a provocative chapter on body size and work capacity. C. Gapalan from the Nutrition Foundation of India completed the volume on a political note, with a report titled "Stunting: Significance and Implications for Public Health Policy." Hence, we are taken full circle with an abundance of exciting and stimulating information along the way.

These are a few of the gems gleaned from this workshop: (1) "Think of stunting (as measured by low height for age) as the cumulative result of many events that disrupt growth

rates in length and cause wasting. Wasting (as measured by low weight for height), on the other hand, is a snapshot reflecting recent disruptive events." (2) As the seasons change so may the velocity of linear growth. In developed countries, children grow faster in height in the spring and less rapidly in the fall. In developing countries, other factors, such as culture and the availability of food, have a greater effect on growth velocity. (3) The intrauterine environment is the major determinant of the length of the newborn, as the fetal genome accounts for only 20% of the variance in birth size. During the first 12 to 24 months of life, genetic influences seem to predominate, provided there are no adverse environmental circumstances, such as lack of food, severe infections, or deprivations. (4) Strenuous maternal activity decreases placental perfusion with a postulated adverse effect on fetal nutrition. (5) If length velocity is slowed in the first 3 years of life (as is so frequently the case in the developing world), the result is a stunted adult (even if growth velocity returns to normal after the third year of life). "If stunting can be prevented until the fifth year, normal growth thereafter may be possible even at current levels of socioeconomic development." (6) Children from the elite groups in developing countries have a growth pattern closer to the National Center for Health Statistics' reference than to the poor of their ethnically similar peers. Thus, the stature of young children in the developing world is more a reflection of poverty than genetics, whereas, in developed countries, genetics plays a greater role. "The growth potential from children around the world is remarkably similar under conditions of adequate nutrition and health." It is the "poverty trap" that prevents the full genetic potential from expression. Not only wasting but also stunting has a positive correlation with childhood mortality and childhood morbidity in that infections are prolonged. There is a close circular relationship between the heights of children and adults in a population and the community's socioeconomic development.

In the last chapter of *Linear Growth Retardation*, Dr Copalan states "There may be academic debates as to what stunting per se does or does not do, but there can be no two opinions about the need for eradication of poverty, which automatically implies the eradication of stunting as well."

The Editorial Board Speaks . . .

Richard W. Blumberg, MD

Dick has been with us since I assumed the editorship of *AJDC*. He has provided keen insight, interesting suggestions, and the wisdom of his long experience in pediatrics, pediatric education, and medicine in general. His retirement has been a most active one. In this issue, Dick presents us with a viewpoint and perspective on the house call. Many of us recall, in our youth (many, many moons ago for some of us), the attention we received as we went through measles, mumps, varicella, and the other afflictions of childhood. A kindly (usually) family physician would attend us at home, in the comfort of our bedrooms, surrounded by familiar objects and loving relatives. It was a different era, a "kinder, gentler" time, to steal a phrase. However, there was less that the physician could do, little need for elaborate equipment or trained personnel, and many other factors that argued for a change to office-based visits as society and medicine changed. Dr Blumberg's observations are cogent for our times.

THE HOUSE CALL—IS IT AN ANACHRONISM THAT HAS SEEN ITS DAY?

During World War II there was a shortage of physicians to serve the civilian population, including pediatricians and general practitioners. This resulted in the beginning of the trend to "bring the child to the office," producing an end to house calls by the 1950s and early 1960s. Apparently, children did not suffer as a consequence, and during the continuing period of physician shortage the practice persisted, since one could see many more children in the office if house calls were not made. While the physician shortage resolved, the custom has continued.

With the renewed interest in home care for the elderly, one is reminded of that era in which pediatricians made house calls. This is a phenomenon that is completely unknown to modern-day pediatricians, and, thus, it might be postulated that for the past 30 years they have not made house calls. Is this good, a custom that should remain archaic and dead not to be renewed? What are the advantages and disadvantages of house calls?

Advantages

1. Patients are seen in their normal environment.
2. The illness, usually associated with fever, is not aggravated by climatic conditions.
3. The physician can be his or her own social service worker and observe environmental conditions in the home.
4. The washing of hands, either in the kitchen or bathroom, provides the opportunity to counsel parents about substances that are potentially dangerous to small children.
5. If there are other children, they also can be examined if the index case would indicate this is necessary.
6. The parent does not have to find someone to stay with the other children while he or she takes the sick one to the physician. This is, of course, in the event there are other children.
7. Transportation is not a problem for the parent.
8. If the mother works and the child is not in a day-care center, she won't have to go home first to take the child to the physician's office. She can meet him or her at home.
9. Seeing the child at home prevents exposure to other children in the physician's office.
10. The child is usually less upset when seen in the home environment.
11. There is less need to prescribe medication over the telephone in the event the parent is unable to bring the child to the physician's office.

12. The physician's willingness to make an occasional house call makes the parent more willing to come to the office on other occasions.

13. The parents are reassured of the physician's availability.

14. An office nurse might make follow-up visits.

Disadvantages

1. The time spent making house calls is not cost-efficient. It takes too much time traveling, combating traffic, and, in some instances, even finding a place to park.

2. Most children are not too ill to be brought to the office, regardless of the weather.

3. More children can be seen with more time allotted if they are brought to a central location.

4. The cost may be less.

5. Diagnostic procedures may be needed that cannot be done at home (ie, chest roentgenography and certain diagnostic laboratory procedures).

An extreme example of home visitation by a pediatrician involved a most unusual but excellent Cincinnati, Ohio, pediatrician who had no office and saw all of his patients in their home, sick or well. Early in the morning, parents "called in" and he made up his itinerary. Most of the patients had scales and measuring rods, and well-child care, including development, was carefully recorded. Immunizations were given at home. In this setup, there was practically no overhead, no secretaries, rent, office, equipment, etc. Therefore, it was not necessary to see large numbers of patients for economic survival.

Will house calls remain archaic? Probably! Perhaps the *Wall Street Journal* (vol CCXIII, 94, May 15, 1989) had the last word on this subject as the following poem illustrates:

Aches and Pains

My doctor makes house calls;
His charges are meager;
His manner is winning;
His patients are eager.
They line up in cadres
For his benediction—
And what I am writing
is sheer science fiction.

Robert Gordon

Growth Hormone Treatment in Children With Sporadic Primary Microcephaly

Gian Luigi Spadoni, MD; Stefano Cianfarani, MD; Sergio Bernardini, MD; Vaccaro Fabrizio, MD; Cinzia Galasso, MD; Brunetto Boscherini, MD

• Four children with sporadic primary microcephaly associated with short stature, delayed bone age, and low growth velocity are described. All of the children showed a normal growth hormone response to standard pharmacological tests but one of the patients had a reduced spontaneous growth hormone nocturnal secretion. Regardless of the results of their somatotrophic function evaluation, the patients were treated with exogenous growth hormone and all of them showed an increase in growth rate.

(AJDC. 1989;143:1282-1283)

Somatic growth is often impaired in children with primary microcephaly.^{1,2} The reason for the high degree of association between small head circumference and growth failure is unknown, but abnormalities of growth hormone (GH) secretion have been reported in some of these children.³

See also pp 1269, 1284, and 1287.

We studied four prepubertal children with sporadic primary microcephaly associated with severe growth retardation and treated them with exogenous GH regardless of the results of their somatotrophic function evaluation.

PATIENTS AND METHODS

The three boys and one girl were prepubertal throughout the duration of the study. Their ages were between 5.0 and 10.7 years. They all had a height of less than -2.5 SDs from normal, delayed bone age, and a growth rate of less than the 10th percentile for bone age. The patients' head circumferences were less than 2 SDs from normal for height age, and they had no anatomic abnormalities other than a small cranium. They had normal

karyotypes, normal neurologic examination results, subnormal mental development, normal cranium roentgenograms except for reduced diameters, normal gestation periods, normal birth weights (except one patient whose birth weight was 2150 g at term), and normal perinatal periods. The auxological data for each patient are shown in Table 1.

Patients' heights were determined on a wall-mounted stadiometer and are expressed as the mean of at least two measurements taken separately by two observers and not differing by more than 0.4 cm. Height velocity was evaluated for a period ranging from 6 months to 1 year.

Height velocity and pubertal stages were compared with the standards of Tanner and Whitehouse.⁴ Bone age was evaluated according to the Greulich-Pyle method.⁵ Head circumference SDs were calculated by plotting the measurements on interracially and internationally applicable head circumference graphs.⁶

None of the children exhibited any sign of malnutrition, hypothyroidism, malabsorption, or any other evident cause for growth retardation. All of the children underwent provocative testing for GH (arginine, 500 mg/kg intravenously, and clonidine, 75 µg/m² of body surface orally). A 12-hour nocturnal spontaneous GH-secretion assessment was also carried out in all of the children: a catheter was inserted into an antecubital vein and 1 mL of blood was drawn every 30 minutes between 8 PM and 8 AM (25 samples).⁷ The insulin-like growth factor 1 concentration was determined on the last sample.

Serum GH levels were measured using a commercial radioimmunoassay kit (hGH Ter-kit, Biodata, Switzerland) and insulin-like growth factor 1 concentrations were de-

termined by a radioimmunoassay kit from the Nichols Institute, Los Angeles, Calif.

After a pretreatment observation period that lasted at least 12 months, the children were treated with biosynthetic GH (Somatotropin, Kabi, Stockholm, Sweden) at a dosage of 0.5 IU/kg per week divided into three intramuscular administrations. This is the dosage generally employed for GH-deficient children. The treatment lasted for a period of 6 months to 1 year. After the completion of therapy, the children were again observed for 6 months.

Informed consent was obtained from the parents of all of the children. Fourteen children with normal growth variants formed a control group for GH nocturnal spontaneous secretion. They all had height between -2 and -2.5 SDs from normal, a normal height velocity (>25th percentile for chronological age), and a familial history positive for short stature or constitutional delay of growth.

RESULTS

Laboratory data for the children with microcephaly and their growth rates before, during, and after GH treatment are summarized in Table 2. As can be seen, all of the children had a normal response (GH peak >10 µg/L) to one or both pharmacological tests. Three patients had a normal mean 12-hour nocturnal GH concentration (normal values of the 12-hour nocturnal mean concentration are >4 µg/L) while one child had a decreased value (1.7 µg/L). Mean GH nocturnal concentrations in the control group ranged from 3.9 to 12.4 µg/L. The lower limit for the normal range of the

*GH indicates growth hormone.

mean 12-hour nocturnal GH concentration is in accordance with other studies.⁷⁻⁹

In only one patient were the insulin-like growth factor 1 values subnormal and they were as low as values generally found in GH deficiency. During treatment the growth rate increased in all patients (the increase in height velocity ranged from +2.0 to +3.4 cm/y) and decreased after withdrawal of GH. Treatment was well tolerated and no adverse effects were observed. A significant negative correlation was found between pretreatment growth velocity (expressed as SD for chronological age) and the increase in height velocity ($r = .99$; $P > .01$).

COMMENT

Pharmacological tests showed a normal GH response in the four children so none of them could be diagnosed as having a "classic" GH deficiency. But one of the patients showed a reduced spontaneous 12-hour GH secretion. Also, other patients with primary microcephaly have been described with reduced GH spontaneous secretion.⁸

All of the children responded to therapy with an increase in growth velocity. An increase of more than 2 cm/y is considered satisfactory by various authors^{10,11}; using this criterion all of the children in this study showed a satisfactory response to GH therapy. The poorest response was shown by the patient who, theoretically, was expected to respond best since he had a reduced spontaneous GH secretion. However, we should also consider that this child was small for gestational age at birth, and the possibility of false-positive results of his spontaneous GH secretion evaluation cannot be excluded.

There is a significant negative correlation

between pretreatment growth velocity and its increase during treatment. These data are also described for normal variants of growth and for GH-deficient children. Thus, height velocity seems to be a useful indicator in predicting the response to therapy and might be a good tool to select non-GH-deficient children to be treated with GH.¹²⁻¹⁴

Our data do not help establish the causes of growth retardation in children with primary microcephaly, but they do suggest that some children with this condition in whom no evident cause for growth retardation has been found may respond to GH therapy if evaluation of somatotropic function has not revealed a GH deficiency. Careful assessment is obviously needed to establish a risk-benefit ratio for the use of GH in children with microcephaly and short stature as in all other non-GH-deficient children.

It must be pointed out that the treatment period in our study was short, and it is not known if the accelerated growth would be sustained with long-term treatment or if the eventual height of these children will be sufficiently improved to justify this demanding and costly treatment. Also, in the case of the carefully controlled long-running studies being carried out in other short non-GH-deficient children (as in girls with Turner's syndrome), the final word is not yet in as to how much improvement there will be in the final height.¹⁵

We employed the same dosage of GH as is generally used for GH-deficient children, but the employment of higher dosages could also be considered. In children with Turner's syndrome, doubling the dosage of GH (from 0.5 to 1 IU/kg per week) has been demonstrated to result in significantly greater height velocity increases with no differ-

ence in advancement of bone age.¹⁶ Obviously, even more careful attention to side effects would be required for such a high-dosage therapeutic regimen.

Diagnostic Limitations of Spontaneous Growth Hormone Measurements in Normally Growing Prepubertal Children

Roberto Lanes, MD

• To evaluate whether the measurement of the spontaneous overnight growth hormone secretion in prepubertal children clearly separated normal children from subjects with growth hormone deficiency, we studied 45 prepubertal normally growing children (10 with normal height and 35 with constitutional growth delay) and compared their overnight growth hormone secretion with that of a group of subjects with either isolated growth hormone deficiency or neurosecretory dysfunction. Peak growth hormone levels (≥ 10 ng/mL) following oral clonidine administration were normal in individuals with normal height, constitutional growth delay, and neurosecretory dysfunction, as was the basal somatomedin C concentration; subjects with growth hormone deficiency had low peak growth hormone levels (< 10 ng/mL) following oral clonidine administration as well as low basal somatomedin C values. The mean 9-hour overnight growth hormone concentration, total growth hormone output, total number of nocturnal pulses, and the mean peak growth hormone response during nocturnal sampling were similar in the normal height and constitutional growth delay groups and significantly greater than those seen in subjects with either growth hormone deficiency or neurosecretory dysfunction. Twelve (26.6%) of 45 normally growing children (4 of 10 normal height and 8 of 35 constitutional growth delay), however, had low overnight growth hormone levels (< 3 ng/mL), which overlapped results obtained in the growth hormone-deficient or neurosecretory dysfunction groups. Frequent overnight growth hormone (GH) sampling does not always separate normal-growing children from those with partial or com-

plete GH deficiency. In our this study over one quarter of the normally growing children had overnight GH levels in the range of children with either GH deficiency or neurosecretory dysfunction. These findings, in addition to the cost and difficulty in performing this test, do not support the measurement of spontaneous GH as a routine test in short but normally growing prepubertal children.

(AJDC.1989;143:1284-1286)

Several articles have suggested that frequent GH sampling over 24 hours or during sleep may be a more clinically relevant assessment of the GH secretory status of a child than the GH response to pharmacologic stimuli.¹⁻³

See also pp 1269, 1282 and 1287.

According to these studies, GH stimulation tests frequently do not reflect the endogenous GH secretion, so that some individuals with normal responses to these tests have a reduced spontaneous secretion of GH and may benefit from treatment with GH.

A recent study,⁴ however, found that the measurement of the spontaneous secretion of GH in prepubertal short children had lower sensitivity and offered no diagnostic advantage over stimulation tests in the diagnosis of GH deficiency.

While studying the overnight GH levels of a control group of normal-height children, we noticed that an appreciable number of their GH values seemed to overlap with those of short children, including those with classical GH deficiency. This prompted us to determine whether we could clearly separate normally growing prepubertal children from those with GH deficiency or neurosecretory dysfunction relying primarily on their spontaneous overnight GH secretion, using 3 ng/mL as a cutoff

point in separating these groups as has been suggested by several studies in children.^{5,6}

METHODS

Forty-five apparently healthy normally growing (≥ 5 cm/y) prepubertal children (34 boys and 11 girls) with a mean (\pm SD) chronologic age of 8.7 ± 2.3 years (range, 6 to 12 years) were studied at the pediatric endocrine clinic of the Hospital Central "Dr Carlos Arvelo." Thirty-five of these subjects were growing at below the fifth percentile for height but maintaining a normal growth velocity (≥ 5 cm/y), and their bone ages were equal to or greater than 2 years delayed compared with their chronologic ages.

The remaining 10 normal-height children (8 boys and 2 girls) had a mean chronologic age of 10.3 ± 2.7 years (range, 7 to 13 years) and were growing adequately (≥ 5 cm/y) above the 10th percentile (range, 25th to 75th percentiles) for height, and had bone ages similar to their chronologic ages. All subjects had appropriate body weight for height.

Normal complete blood cell counts, erythrocyte sedimentation rates, routine blood chemistry study results, and thyroid function test results were obtained prior to GH testing in all patients and controls. Bone ages were determined by hand films according to the method of Greulich and Pyle.⁷

After an overnight fast, all patients received a single oral dose of $100 \mu\text{g}/\text{m}^2$ of clonidine early in the morning, and blood samples for GH determination were drawn in a recumbent position at 0, 60, and 90 minutes thereafter; blood pressure was measured every half hour. In addition, a single plasma specimen was obtained at the time of initial sampling for measurement of somatomedin C. For the GH-release studies during sleep, blood samples were drawn from an indwelling venous catheter every 30 minutes from 9 PM until 6 AM.

Patients were admitted 4 hours before the overnight sampling and had a balanced dinner at 6 PM. An effort was made to avoid stress and to encourage normal activity during this period. Lights were turned off at 9 PM, and each patient's status was recorded

as awake or asleep; all patients had a minimum of 7 hours of observed sleep. The nocturnal study was begun on the same day, or a few days after, the clonidine was given.

Samples were stored at -20°C . Specific radioimmunoassay techniques were used for the determination of serum GH using chemically prepared human GH double-antibody radioimmunoassay (RIA Kits, Diagnostic Products Corp, Los Angeles, Calif) as previously described.⁸ All samples were assayed in duplicate by the same laboratory technician. Blood for SMC determination was collected in ethylenediaminetetraacetic acid tubes, and plasma was frozen and shipped to Nichols Institute in Los Angeles for SMC radioimmunoassay.

Growth hormone concentrations equal to or greater than 10 ng/mL after subjects took oral clonidine were considered normal. Integrated overnight GH concentrations were determined by obtaining the mean of all measurements for each child. We arbitrarily considered that a minimum GH pulse must exceed 5 ng/mL. Comparison of integrated overnight GH concentrations and of basal SMC levels of the population studied was accomplished by ANOVA. Total GH output was estimated by measuring the area under the curve vs a 9-hour time curve, and comparison of both groups was done with the unpaired *t* test and the Mann-Whitney *U* Test. Results are expressed as mean \pm SD.

Results of our patients' GH testing were compared with those of a group of seven children with isolated GH deficiency (6 boys and 1 girl; chronologic age, 9.1 ± 3.5 years), serum GH response to at least two different provocative tests of less than 10 ng/mL, growth velocity of less than 4 cm/y, delayed skeletal age, low plasma somatomedin C level, and low mean 9-hour overnight GH concentrations (<3 ng/mL) (Table); and with those of a group of seven children with neurosecretory dysfunction (6 boys and 1 girl; chronologic age, 10.3 ± 3.1 years), growth velocity of less than 4 cm/y, delayed skeletal age, peak serum GH response to one or more provocative tests of equal to or greater than 10 ng/mL, and low mean 9-hour overnight GH levels (<3 ng/mL) (Table).

The studies were performed with the approval of the hospital research and publications committee, and with informed parental consent.

RESULTS

All 45 normally growing subjects as well as all patients with neurosecretory dysfunction were able to increase their GH levels to equal to or greater than 10 ng/mL after oral clonidine ingestion. Mean peak GH concentrations of 22.0 ± 8.3 ng/mL, 17.8 ± 6.7 ng/mL, and

Group	Mean Overnight GH Levels, $\mu\text{g/L}$	Total Basal GH Output, U†	Total Nocturnal GH Pulses, ng/mL	Mean Peak Nocturnal GH Level, ng/mL
Children with constitutional growth delay	4.2 ± 1.8	224 ± 92	3.5 ± 0.7	13.0 ± 1.2
Normal-height children	4.4 ± 2.8	222 ± 135	3.3 ± 1.3	13.2 ± 1.3
Children with neurosecretory dysfunction	2.0 ± 0.4	41 ± 5	1.9 ± 0.4	9.0 ± 1.3
Children with GH deficiency	1.6 ± 0.2	25 ± 6	1.8 ± 0.4	5.2 ± 1.1

*Values are expressed as mean \pm SD. GH indicates growth hormone.

†Total GH output was estimated by measuring the area under the curve vs a 9-hour time curve.

Mean overnight growth hormone (GH) levels in normal-height children, children with constitutional growth delay (CGD), and children with GH deficiency and neurosecretory dysfunction. The solid lines represent the average value in each subject group.

16.8 ± 5.3 ng/mL were obtained by the normal height, constitutional growth delay (CGD), and neurosecretory dysfunction groups, respectively, 60 minutes after oral clonidine ingestion. Mean peak GH levels were 4.1 ± 1.2 ng/mL in the GH-deficient group after clonidine stimulation. Basal somatomedin C levels were 1.0 ± 0.5 U/mL, 1.1 ± 0.3 U/mL, and 1.0 ± 0.4 U/mL in the normal-height children, those with CGD, and in subjects with neurosecretory dysfunction, respectively. The mean somatomedin C level in the GH-deficient children was significantly reduced compared with the other three groups (0.4 ± 0.1 U/mL; $P < .01$).

Mean 9-hour overnight GH concentrations, total basal GH output, number of nocturnal GH pulses, and mean peak GH response during nocturnal sampling of normal-height children and subjects with CGD were similar and significantly larger than those seen in the groups with neurosecretory dysfunction and GH deficiency ($P < .001$) (Table and Figure).

However, 12 (26.6%) of 45 normally growing children had low mean 9-hour overnight GH levels, so that 4 (40%) of 10 normal-height children and 8 (22.9%) of 35 subjects with CGD had mean 9-hour overnight GH concentrations of less than 3 ng/mL, which overlapped

with levels obtained in the 7 patients with neurosecretory dysfunction and in 7 GH-deficient subjects (Figure).

COMMENT

Several recent reports^{5,6} have suggested that in addition to clinical findings and GH provocative testing, a mean 24-hour or overnight GH level of 3 ng/mL could be used as a cutoff point in separating normally growing children (≥ 3 ng/mL) from those with classical GH deficiency or neurosecretory dysfunction (< 3 ng/mL).

In this study we considered both normal-height children and children with CGD as part of a healthy normal group, since subjects in both these groups were growing normally at equal to or greater than 5 cm/y and since in a previous report we were unable to find any difference in the mean GH secretion of children with CGD and that of a normal-height control population when we evaluated their GH response to provocative testing, their spontaneous overnight GH secretion, and their basal somatomedin C levels.⁸ Similar results have recently been reported by Rose et al.⁴

We found that 12 (26.6%) of the 45 normally growing children had a mean overnight GH concentration less than 3 ng/mL, overlapping with values obtained by patients with GH deficiency and neurosecretory dysfunction. These low GH levels were detected in a fair number of both normal-height and CGD children (40% and 22.9%, respectively). By using overnight GH sampling as the

sole means of evaluating the GH status of normally growing children, over one quarter of this population would have been considered to have some form of GH deficiency (partial or complete).

We only evaluated overnight GH levels since the diagnostic validity of overnight GH sampling has been confirmed by several recent reports,^{4,6,9} which, based on the excellent correlation between overnight and 24-hour GH concentrations, suggested that overnight testing could substitute for 24-hour sampling for most diagnostic purposes.⁶

In this study we limited ourselves to studying the spontaneous GH secretion of a group of prepubertal children. We do not know whether pubertal subjects, in whom sexual hormones have been shown to increase spontaneous secretion of GH,^{10,11} will also show a significant overlap in GH levels sampled frequently. Both obesity and depression are factors known to decrease the 24-hour integrated GH concentrations⁶; however, all of our patients were healthy, came, as far as we could tell, from stable environments, and had an appropriate body weight for height.

Frequent GH sampling is apparently not as sensitive as provocative testing in the diagnosis of GH deficiency,⁴ and, as shown in this study, if it is used as the only laboratory tool for determining the GH status of individual short but normally growing children, it can give an appreciable number of false-positive results.

In addition, Donaldson et al⁹ recently reported that a single overnight GH se-

cretory profile may not reflect physiological GH production, as significant variation in GH secretory profiles on consecutive nights was found. All of these data, compounded by the cost and difficulty in performing this test, do not support the measurement of spontaneous GH as a routine diagnostic test in prepubertal children.

Both provocative testing and measurement of the spontaneous GH levels in prepubertal children have been shown to have a margin of error. It is known that normal subjects may not respond to any single stimulus for GH: Penny et al¹² found that 20% of normal subjects did not respond to arginine and 20% did not respond to insulin, and my colleagues and I¹³ found a lack of response to exercise in 11.9% of normal children. This study demonstrates how over 25% of normally growing prepubertal children may have low spontaneous overnight GH levels.

It may be concluded that no one testing procedure for GH secretion alone, direct (overnight secretion, 24-hour integrated secretion, provocative stimuli testing) or indirect (somatomedin C), is able to identify the individual who is GH deficient. Only when the testing procedures are combined with a growth rate that is less than the minimal normal growth rate per year can the individual who is GH deficient be identified. Additionally, it should be noted that a satisfactory assessment of a child's growth cannot be made over a period of less than 1 year.

Criteria for Recognition of the Growth-Inefficient Child Who May Respond to Treatment With Growth Hormone

Giuseppe Saggese, MD, Graziano Cesaretti, MD

• In this study three groups of short children composed of 104 subjects (61 boys, 43 girls) were evaluated for spontaneous secretion of growth hormone (GH). Group 1 consisted of 10 subjects (6 boys, 4 girls) with "classic" GH deficiency. Group 2 consisted of 31 subjects (17 boys, 14 girls) with "nonclassic" GH deficiency. Group 3 consisted of 63 subjects (38 boys, 25 girls) with short normal stature. Blood samples were drawn every 20 minutes over 24 hours, and the mean GH concentration, nocturnal GH concentration, diurnal GH concentration, pulse amplitude, and number of pulses with a GH peak above 5 $\mu\text{g/L}$ were determined. The values for mean height, height velocity, bone age to chronological age ratio, somatomedin C concentration, GH concentration, nocturnal GH concentration, diurnal GH concentration, pulse amplitude, and number of pulses with a GH peak over 5 $\mu\text{g/L}$ were significantly greater in group 3 than in group 2, and these same values, except for the mean diurnal GH concentration, were greater in group 2 than in group 1. The mean GH concentration correlated with the mean nocturnal GH concentration. Subjects in groups 1 and 2 were treated with GH for 1.23 ± 0.53 years (mean \pm SD). All the group 1 subjects and 27 (87%) of the group 2 subjects responded with an increase in height velocity greater than 2 SDs per year of therapy. In conclusion, 87% of subjects with a normal GH response to provocative stimuli testing who had a mean height velocity of less than 4 cm/y, mean height lower than the third percentile, mean bone age to chronological age ratio of less than 0.8, and mean GH concentration less than 3 $\mu\text{g/L}$ responded to GH therapy.

(AJDC. 1989;143:1287-1293)

Until recently, treatment of short children with growth hormone (GH) has been limited to subjects with an im-

See also pp 1269, 1282, and 1284.

paired height velocity (HV) and unequivocal GH deficiency demonstrated by blunted responses on at least two

provocative stimuli tests ("classic" GH deficiency).¹

The availability of virtually unlimited supplies of biosynthetic GH offers the physician new therapeutic perspectives.^{2,9} Indeed, in the last few years, many short children who did not fulfill the rigid criteria of GH deficiency have been treated with GH, and in many but not all instances an increased HV has been obtained.¹⁰⁻²⁵

Growth hormone is a potent agent with a variety of important metabolic actions,³ and some adverse effects may occur during GH administration, especially in children without GH deficiency.^{2,3,26,27} Because ethical and economical issues also have to be taken into account, the problem of how to select short children for GH treatment is still unresolved.¹⁸ Moreover, a short-term increase in HV does not necessarily result in an improvement in long-term growth, with an increased adult height.^{8,9,20,28} When the expectation of a taller height is not reached, children and parents may become psychologically discouraged. Therefore, a detailed investigation of short children who are potentially able to respond to GH therapy with improved linear growth is advocated.

Recent studies have dealt with the usefulness of the evaluation of spontaneous GH secretion as a very sensitive approach in diagnosis for short children.²⁹⁻³⁷ Nevertheless, in the opinion of some, this procedure has less diagnostic accuracy than conventional provocative GH testing.³⁸

In the present study we evaluate whether short children with subnormal spontaneous GH secretion may benefit from GH therapy and whether there is a relationship between the 24-hour mean GH concentration and other hormonal measurements or auxologic features.

PATIENTS AND METHODS

Patients

One hundred four (61 boys, 43 girls) growth-retarded but otherwise healthy children with normal birth weight and length

were selected for the study; their chronological age (CA) at the time of evaluation was 8.89 ± 1.68 years (mean \pm SD).

Height (mean of three measurements using a wall-mounted stadiometer), weight, and HV (evaluated during the year before the examination) were evaluated. Bone age (BA) and predicted adult height were determined according to the method of Tanner et al.³⁹ To allow a comparison between different ages and between sexes, height and HV were expressed as SD scores: $(x - \bar{x})/\text{SD}$, where x is the observed value, \bar{x} is the mean value of height and HV for CA and BA, respectively, and SD is the standard deviation for CA and BA, respectively, using the standards of Tanner et al.^{40,41} Height age (HA) was also evaluated according to the methods of Tanner et al.⁴⁰

Auxologic features were considered "pathologic" if HV was more than 1.5 SDs below normal and the BA/CA ratio was lower than 0.8; auxologic features were considered "nonpathologic" if HV was less than 1.5 SDs below normal and the BA/CA ratio was greater than 0.8.

The height of all subjects was more than 1.8 SDs below normal (2.35 ± 0.39 SDs below normal). Weight results were within 1 SD of the mean for height age.⁴⁰ The children were selected to examine mainly subjects with pathologic auxologic features; therefore, 84 children with pathologic auxologic features (HV: 3.86 ± 0.65 cm/y, 2.36 ± 0.64 SDs below normal; BA/CA ratio: 0.72 ± 0.06) and 20 children with nonpathologic auxologic features (HV: 4.55 ± 0.45 cm/y, 1.32 ± 0.44 SDs below normal; BA/CA ratio: 0.94 ± 0.05) were enrolled in the study. Psychosocial deprivation syndrome and other endocrine or nonendocrine systemic diseases were ruled out. Results of the karyotype examination, carried out in all girls, were normal. At the time of the 24-hour study, pubertal staging ranged from prepubertal to stage II, according to the criteria of Tanner.⁴²

The study was approved by the Ethical Committee of the Medical Faculty, University of Pisa, Italy. Informed consent for the study was obtained from parents and any child over 12 years old.

All children underwent two pharmacologic stimuli tests, levodopa administration (500 mg per 1.73 m^2) and the insulin tolerance test (0.1 U of regular insulin per kilogram intravenously). Blood samples were drawn for GH measurement every 20 minutes for 2 hours during both tests. During the insulin tolerance test, adequate hypoglycemia, ie, blood

Accepted for publication March 20, 1989.

Reprint requests to Endocrine Unit, Department of Pediatrics, University of Pisa, Via Roma 85, 56100 Pisa, Italy (Dr Saggese).

glucose levels less than half the basal level and/or lower than 2.2 mmol/L, was achieved in all children.

Serum somatomedin C/insulinlike growth factor I was evaluated four times at 8 AM at monthly intervals⁴³ and expressed as a mean value.

24-Hour GH Evaluation

The children were admitted on the day before the spontaneous GH evaluation, which consisted of drawing 1 mL of blood through an indwelling intravenous catheter (placed in a forearm vein 1 hour before beginning the study) every 20 minutes over 24 hours (from 8 AM to 8 AM of the following day). Subjects were fed at 7 AM, 12 PM, 4 PM, and 8 PM and were encouraged to continue their normal activities, such as walking, playing, or reading.

All 73 samples were measured for each child, and the following secretory measurements were evaluated: (1) 24-hour mean GH concentration, the arithmetic mean of all 73 values; (2) nocturnal 12-hour mean GH concentration, the arithmetic mean of 37 samples from 8 PM to 8 AM of the following day; (3) diurnal 12-hour mean GH concentration, the arithmetic mean of 37 samples from 8 AM to 8 PM; (4) number of pulses with a GH peak greater than 5 µg/L; and (5) mean pulse amplitude, the arithmetic mean of all GH peaks greater than 1.5 µg/L.

GH Therapy

No child had received previous hormonal treatment.

Subjects with a mean GH concentration lower than 3 µg/L were treated with GH, 12 IU/m² per week, divided into three subcutaneous injections. During GH therapy, height, weight, HV, and BA were evaluated every 6 months, while the following values were determined every 3 months: glycemia, transaminases, cholesterol, triglycerides, white blood cell counts, thyroxine, and thy-

rotropin. The change of auxologic features during GH therapy have been expressed as the change in the SD score for height, the change in HA, the ratio of the change in HA to change in CA ($\Delta HA/\Delta CA$), the change in the SD score for HV, the ratio of the change in HA to the change in BA ($\Delta HA/\Delta BA$), and the change in predicted adult height; some of these have also been expressed as the change per year to allow a comparison between different periods of GH therapy.

Hormonal Assays

All 73 samples of the 24-hour evaluation for every child were measured in duplicate for GH in one assay by a two-site immunoradiometric assay using two different antibodies in excess (Pharmacia Diagnostics AB, Uppsala, Sweden). The within-assay and total-assay coefficients of variation for GH values were 2.5% to 5.1% and 3.5% to 5.6%, respectively. Cross-reactivity was less than 1% for human placental lactogen and prolactin. The sensitivity of the GH assay was 0.2 µg/L; values below 0.25 µg/L were considered to be 0.25 µg/L.

Somatomedin C levels were determined

by a radioimmunoassay kit (Diagnostic Systems Laboratories Inc, Webster, Tex). The sensitivity was 8 IU/L, while the cross-reactivity was 8% for insulinlike growth factor II. The intra-assay and the interassay coefficients of variation were 2.7% to 9.2% and 7% to 10%, respectively.

Statistical Analysis

The statistical methods used to analyze the hormonal data and auxologic features were Student's *t* test for paired and unpaired subjects and linear regression analysis.

RESULTS

The subjects were subdivided into three groups according to their GH responses to provocative stimuli testing (Table 1) and their mean GH concentration. Group 1 consisted of 10 subjects (6 boys, 4 girls) who had a diagnosis of classic GH deficiency on the grounds of two provocative stimuli test results that included a peak GH concentration lower than 10 µg/L and pathologic auxologic features; the mean GH concentration

Table 1.—Hormonal Data of Examined Children*

Group	No. of Patients		Growth Hormone, µg/L		
			Insulin Tolerance Test	Levodopa Administration	Somatomedin C, IU/L
1	10	Mean ± SD	3.3 ± 1.4	3.0 ± 1.9	270 ± 100
		Range	0.5-5.7	0.9-6.5	120-410
2	31	Mean ± SD	14.0 ± 7.8	13.6 ± 6.6	460 ± 160
		Range	2.3-30.8	2.6-25.4	210-750
3	63	Mean ± SD	15.8 ± 6.3	13.6 ± 7.0	900 ± 380
		Range	4.2-27.1	2.0-25.9	250-2330

*For group 1 vs group 2, *P* < .001 for the insulin tolerance test and levodopa administration, *P* < .002 for somatomedin C; group 1 vs group 3, *P* < .001 for the insulin tolerance test, levodopa administration, and somatomedin C; and group 2 vs group 3, *P* was not significant for the insulin tolerance test and levodopa administration and *P* < .001 for somatomedin C. For the insulin tolerance test vs levodopa administration, *P* was not significant in all the groups.

Table 2.—Spontaneous Growth Hormone Study of Examined Children*

Group	No. of Patients		Growth Hormone Concentration, µg/L			No. of Pulses With a Growth Hormone Peak > 5 µg/L	Mean Pulse Amplitude, µg/L

		Range	3.07-9.57	3.16-11.02	0.68-8.56	1-8	5.92-14.46

*For group 1 vs group 2, *P* < .02 for mean growth hormone concentration and mean nocturnal growth hormone concentration, *P* was not significant for mean diurnal growth hormone concentration, *P* < .001 for number of pulses with a growth hormone peak greater than 1.5 µg/L, and *P* < .005 for mean pulse amplitude; group 1 vs group 3, *P* < .001 for all measurements; and group 2 vs group 3, *P* < .001 for all measurements. For mean growth hormone concentration vs mean nocturnal growth hormone concentration, *P* was not significant for group 1, *P* < .005 for group 2, and *P* < .001 for group 3. For mean growth hormone concentration vs mean diurnal growth hormone concentration, *P* was not significant for group 1 and *P* < .001 for groups 2 and 3. For mean nocturnal growth hormone concentration vs mean diurnal growth hormone concentration, *P* was not significant for group 1 and *P* < .001 for groups 2 and 3.

was lower than 3 $\mu\text{g/L}$. Group 2 consisted of 31 subjects (17 boys, 14 girls) with a diagnosis of nonclassic GH deficiency; they had a normal response (peak GH concentration $>10 \mu\text{g/L}$) to levodopa administration and/or an insulin tolerance test (13 subjects responded to both tests; 18 responded to one test)

Twenty-four-hour mean growth hormone (GH) concentrations in the 104 examined short children. Group 1 ($n=10$) includes children with classic GH deficiency; group 2 ($n=31$), children with nonclassic GH deficiency (peak GH concentration $>10 \mu\text{g/L}$ in response to one or two provocative tests and mean GH concentration $<3 \mu\text{g/L}$); and group 3 ($n=63$), children with short normal stature (peak GH concentration $>10 \mu\text{g/L}$ in response to one or two provocative tests and mean GH concentration $>3 \mu\text{g/L}$). Solid circle indicates short children with a bone age to chronological age ratio lower than 0.8 and a height velocity more than 1.5 SDs below normal; open circle, short children with a bone age to chronological age ratio greater than 0.8 and a height velocity less than 1.5 SDs below normal.

and a mean GH concentration lower than 3 $\mu\text{g/L}$. Group 3 consisted of 63 subjects (38 boys, 25 girls) with a diagnosis of short normal stature; they had a normal response (peak GH concentration $>10 \mu\text{g/L}$) to levodopa administration and/or an insulin tolerance test (26 subjects responded to both tests; 37 responded to one test) and a mean GH concentration greater than 3 $\mu\text{g/L}$.

All the subjects in groups 1 and 2 were prepubertal. Somatomedin C values and peak GH concentrations in response to insulin tolerance tests and levodopa administration in group 1 were significantly lower than those in groups 2 and 3 ($.001 < P < .02$). The only difference between groups 2 and 3 was increased somatomedin C levels in group 3 ($P < .001$).

Results of the spontaneous GH secretion study (mean GH concentration, mean nocturnal GH concentration, mean diurnal GH concentration, number of pulses with a peak GH concentration over 5 $\mu\text{g/L}$, and mean pulse amplitude) of the examined children are reported in Table 2. The individual values for mean GH concentration are shown in the Figure. In all children, the mean diurnal GH concentration was lower than the mean nocturnal GH concentration. All GH measurements in group 2 except mean diurnal GH concentration were significantly greater ($.001 < P < .02$) than those in group 1, whereas all GH values in group 3 were significantly greater ($P < .001$) than those in group 2, so that GH measurements in group 2 were intermediate compared with those in groups 1 and 3.

Furthermore, in groups 2 and 3 but not in group 1, the mean GH concentration was significantly lower than the mean nocturnal GH concentration

($.001 < P < .005$) and significantly greater than the mean diurnal GH concentration ($P < .001$), and, obviously, the mean nocturnal GH concentration was significantly greater than the mean diurnal GH concentration ($P < .001$).

A comparison of auxologic features among the three groups is given in Table 3. In addition to the patients with classic GH deficiency (group 1), all the subjects with nonclassic GH deficiency (group 2) had pathologic auxologic features, while all 20 subjects with nonpathologic auxologic features together with the remaining 43 subjects with pathologic auxologic features (short normal children, group 3) had a mean GH concentration greater than 3 $\mu\text{g/L}$. Values in group 2 were significantly greater ($P < .001$ for SD score for height, $P < .002$ for BA/CA ratio, $P = .002$ for SD score for HV) than in group 1 and significantly lower ($P < .001$ for SD scores for height and HV and for BA/CA ratio) than in group 3. Obviously, values in group 3 were significantly greater ($P < .001$ for SD scores for height and HV and for BA/CA ratio) than in group 1.

The correlations between mean GH concentration and other GH measurements, somatomedin C concentration, and auxologic features were as follows: mean nocturnal GH concentration: $r = .979$, $P < .001$ (linear regression equation: $y = 1.19x + 0.09$); mean diurnal GH concentration: $r = .951$, $P < .001$ ($y = 0.78x - 0.01$); somatomedin C concentration: $r = .794$, $P < .001$ ($y = 0.22x - 0.16$); mean pulse amplitude, $r = .832$, $P < .001$; number of pulses with a GH peak greater than 5 $\mu\text{g/L}$, $r = .637$, $P < .001$; SD score for HV: $r = .499$, $P < .001$; SD score for height: $r = .414$, $P < .001$; BA/CA ratio:

Table 3.—Comparison of Auxologic Features Among Examined Children*

Group	No. of Patients		CA, y	Height		BA, y	BA/CA Ratio	Height Velocity

*CA indicates chronological age; BA, bone age. For group 1 vs group 2, P was not significant for CA, $P < .001$ for SD score for height, $P < .002$ for BA/CA ratio, and $P = .002$ for SD score for height velocity; group 1 vs group 3, $P < .02$ for CA and $P < .001$ for SD score for height, BA/CA ratio, and SD score for height velocity; and group 2 vs group 3, P was not significant for CA and $P < .001$ for SD score for height, BA/CA ratio, and SD score for height velocity.

$r = .297$, $P < .02$; peak GH concentration during insulin tolerance test: $r = .290$, $P < .05$; and peak GH concentration after levodopa administration: $r = .232$, P , not significant.

By analysis of the regression equations for the mean GH concentration (x) compared with the mean nocturnal GH concentration (y) and the mean diurnal GH concentration (y), the values that corresponded to a mean GH concentration of $3 \mu\text{g/L}$ were $3.66 \mu\text{g/L}$ for mean nocturnal GH concentration and $2.33 \mu\text{g/L}$ for mean diurnal GH concentration. If we use these values as cutoff points to separate subjects with a "normal" mean GH concentration from those with a "low" mean GH concentration, the specificity and sensitivity⁴⁴ of the nocturnal and diurnal evaluations were as follows: The mean nocturnal GH concentration was normal in 61 of 63 subjects who had a mean GH concentration greater than $3 \mu\text{g/L}$ (specificity, 97%) and pathologic in 38 of 41 subjects with a mean GH concentration lower than $3 \mu\text{g/L}$ (sensitivity, 93%). The mean diurnal GH concentration was normal in 56 of 63 subjects with a mean GH concentration greater than $3 \mu\text{g/L}$ (specificity, 89%) and pathologic in 36 of 41 subjects with a mean GH concentration lower than $3 \mu\text{g/L}$ (sensitivity, 88%).

On the basis of the regression equation for the mean GH concentration and the somatomedin C concentration, the somatomedin C value that corresponded to a mean GH concentration value of $3 \mu\text{g/L}$ was 500 IU/L. The somatomedin C concentration was below 500 IU/L in all children in group 1 (100%), in 19 (61%) of 31 children in group 2, and in 12 (19%) of 63 children in group 3 (only 1 child among those with nonpathologic auxologic features had a somatomedin C concentration below 500 IU/L). The somatomedin C concentration was also highly correlated ($P < .001$) with the SD score for HV ($r = .583$), the SD score for height ($r = .540$), the BA/CA ratio ($r = .447$), and the CA ($r = .344$). The SD score for HV was also correlated with the mean pulse amplitude ($r = .604$, $P < .001$) and the number of pulses with a GH peak greater than $5 \mu\text{g/L}$ ($r = .526$, $P < .001$).

The effects of GH therapy on the 41 treated subjects are shown in Table 4. At the time of this report, 8 subjects had been receiving therapy for 24 months,

Table 4.—Comparison of Auxologic Features							
Group	No. of Patients	Therapy Period, y	Height After Growth Hormone Therapy				
			cm	SD Score	ΔSD Score	ΔSD Score/y	
1	10	Mean±SD	1.25±0.54	116.3±10.0	-2.46±0.37	+0.77±0.27	+0.66±0.19
		Range	.5-2.0	99.7-130.3	-2.91-1.84	0.42-1.10	0.42-1.00
2	31	Mean±SD	1.23±0.53	124.8±6.8	-1.84±0.32	+0.60±0.33	+0.49±0.21
		Range	.5-2.0	109.1-137.5	-2.26-1.50	+0.13-1.24	+0.21-1.24

*HA indicates height age; CA, chronological age; and BA, bone age. $P < .001$ for both groups for SD score for height after growth hormone treatment compared with before growth hormone treatment and for SD score for height velocity during growth hormone treatment compared with before growth hormone

12 subjects for 18 months, 12 subjects for 12 months, and 9 subjects for 6 months (mean \pm SD treatment period, 1.23 ± 0.53 years). No subject had onset of pubertal development during treatment. There was no statistical correlation between the mean GH concentration and the SD score for HV during therapy. The SD scores for both height and HV were significantly higher ($P < .001$) during the treatment period than before treatment in both groups 1 and 2.

Subjects in group 1 had significantly greater values in the SD score for height ($P < .001$), in the change in the SD score for height ($P < .05$), in the HV (centimeters per year, $P < .05$), and in the change in the SD score for HV ($P < .05$) compared with group 2. The weight of all subjects remained within 1 SD of the mean for HA.

If the individual auxologic effects are adjusted to the different length of therapy, our data indicate that all 10 children in group 1 and 26 of the 31 children in group 2 had an increase in height greater than 0.3 SDs per year and that all 10 children in group 1 and 27 of 31 children in group 2 had an increase in HV greater than 2 SDs per year. Therefore, all children with classic GH deficiency and 27 children (87%) with nonclassic GH deficiency had a satisfactory response to GH therapy.

The predicted adult height was significantly higher ($P < .001$) after the treatment than before: 158.5 ± 5.0 cm vs 152.8 ± 3.4 cm in group 1 and 163.1 ± 4.7 cm vs 157.8 ± 4.0 cm in group 2, with a gain of 5.59 ± 2.94 cm (4.55 ± 1.18 cm per year of therapy) in group 1 and 5.24 ± 2.69 cm (4.53 ± 1.89 cm per year of therapy) in group 2 (P , not significant between the two groups). During the period of treatment, the Δ HA/ Δ BA ra-

tio was 1.28 ± 0.25 in group 1 and 1.39 ± 0.24 in group 2 (P , not significant between the two groups). The only children (in group 2) with a Δ HA/ Δ BA ratio lower than 1 (0.90 during 18 months of therapy) showed an improvement in predicted height of 3.30 cm. Only two children (both in group 2) had an improvement in predicted adult height of less than 2 cm per year of therapy: 1.84 and 1.68 cm/y.

During GH therapy, blood glucose, transaminase, cholesterol, triglyceride, thyroxine, and thyrotropin values remained within the normal range in all children.

COMMENT

Until recently, the limited supplies of pituitary-derived GH have dictated the criteria regulating the administration of the hormone, so that only short children who fulfilled the rigid criteria of classic GH deficiency have been treated. Now we are entering an era in which virtually unlimited supplies of GH are offered to the physician. The logical consequences will be both better management of GH-deficient children and an attempt to promote growth in short children who did not fulfill the above-mentioned criteria. Indeed, some recent studies have clearly demonstrated a good response in HV when short, non-GH-deficient children were given GH.^{10-25,45}

Which short children should receive GH must also be considered from the ethical and economic points of view. The long-term side effects of GH are not known, nor do we know if a short-term increase in growth is a good indicator of a long-term result. These arguments strongly support a careful selection of short children who, though they do not have a GH deficiency by classic criteria, are growing slowly because of possible

Before and After Growth Hormone Therapy*

treatment. For group 1 vs group 2, $P < .001$ for SD score for height; P was not significant for Δ SD score for height, Δ HA, Δ HA/ Δ CA, SD score for height velocity, and Δ SD score for height velocity per year; and $P < .05$ for Δ SD score for height per year, height velocity, and Δ SD score for height velocity.

decreased GH secretion.

Even if our results do not address the question whether short children with normal, spontaneous GH secretion (mean GH concentration higher than the conventional cutoff of 3 μ g/L) respond to GH therapy, we have demonstrated that the selection of short children based on auxologic features and on the evaluation of spontaneous GH secretion is a reliable method of finding short children who may benefit from GH therapy. Furthermore, this approach is able to select, among the short children who probably would respond to a trial with GH, only those presenting a rationale for GH therapy, ie, a reduced GH secretion and pathologic auxologic features.

Our study has demonstrated that reduced spontaneous 24-hour GH secretion may be detected, in addition to all children with classic GH deficiency (group 1), in short children with pathologic auxologic features, in spite of their normal responses to pharmacologic stimuli (group 2, nonclassic GH deficiency). This condition probably includes the so-called *GH neurosecretory dysfunction*,^{30,46} even if, as suggested by Chalew et al,²¹ this term does not seem to be suitable, because a specific physiopathologic dysregulation in GH secretion has not been demonstrated yet. The normal responses to pharmacologic stimuli in these children might be explained by a subtle abnormality in regulation of GH secretion that may impair only spontaneous GH secretion without altering the responses to conventional provocative testing.

In our children with nonclassic GH deficiency, all spontaneous GH measurements were significantly lower than those of subjects with a mean GH concentration greater than 3 μ g/L

(group 3, short normal children), and all GH values except for mean diurnal GH concentration were significantly higher than those of children with classic GH deficiency. Similarly, Costin and Kauffman³³ and Shulman and Bercu³⁶ have demonstrated intermediate values of spontaneous GH measurements in children with GH neurosecretory dysfunction.

In our study the correlation between mean GH concentration and peak GH concentration after provocative testing was absent for levodopa administration and, as shown by Zadik et al³¹ and Jesuran et al,⁴⁷ modest for insulin tolerance testing. Among the 41 children with a low mean GH concentration, only the 10 with classic GH deficiency (group 1) had low peaks after both pharmacologic stimuli, while the other 31 children with a mean GH concentration lower than 3 μ g/L had either one or two normal GH peaks. Therefore, children with a low spontaneous GH secretion are more numerous than those who may be identified by low responses to provocative testing; Zadik et al³¹ showed that 45% of short children with normal GH peaks in response to pharmacologic stimuli had a spontaneous GH concentration within the range of GH deficiency.

On the other hand, Rose et al³⁸ have recently shown that evaluation of spontaneous GH secretion has less diagnostic accuracy than provocative testing because only 57% of the children given a diagnosis of classic GH deficiency on the basis of pharmacologic stimuli had abnormal responses to the 24-hour spontaneous GH examination. Some of their patients with GH deficiency were growing at 10 cm/y or had a height increase of 1.5 SDs; moreover, some of Rose and colleagues' idiopathic short children had

a very subnormal HV and low somatomedin C values. Nevertheless, falsely low GH responses to provocative testing may occur in normal children and, on the contrary, normal GH values may occur after stimuli in subjects with nonclassic GH deficiency (low spontaneous GH secretion regardless of normal responses to stimuli), some of whom may have mean GH concentrations overlapping those of children with classic GH deficiency.

In our study, mean GH concentration correlated with pretreatment SD score for HV ($P < .001$), SD score for height ($P < .001$), and BA/CA ratio ($P < .02$). Similarly, Albertsson-Wikland and Rosberg³⁷ demonstrated a high correlation between GH secretion and SD score for height, whereas Brook et al,^{8,48} plotting the SD score for HV against the log of the sum of the GH pulse amplitudes, obtained a linear regression. Also, our correlation values of SD score for HV were slightly higher for both the mean pulse amplitude ($r = .604$) and the number of pulses with a GH peak greater than 5 μ g/L ($r = .527$) than for the mean GH concentration ($r = .492$). On the other hand, Costin and Kaufman,³³ Spiliotis et al,³⁰ and Adlar et al⁴⁹ did not find any correlation between mean GH concentration and growth rate or BA.

The correlation between GH secretion and growth has led to the suggestion of treating short children only on the basis of auxologic features regardless of hormonal measurements.^{8,23} However, in our study we have shown that auxologic features alone are not reliable enough to select short children with subnormal mean GH concentrations. Even if children with a mean GH concentration lower than 3 μ g/L (group 2) had, as a group, auxologic features that were statistically different from those of children with a mean GH concentration greater than 3 μ g/L (group 3; $P < .001$ for SD score for height, BA/CA ratio, and SD score for HV), and even if the mean GH concentration correlated with the BA/CA ratio, height, and HV, there was an overlap in auxologic features between the two groups. Indeed, 43 children in group 3 had a mean GH concentration greater than 3 μ g/L in spite of their pathologic auxologic features (BA/CA ratio < 0.8 and SD score for HV more than 1.5 SDs below normal). In any case, a low mean GH con-

centration was not found in any of the 20 short children with nonpathologic auxologic features (short familial stature?).

Short children with a low mean GH concentration (groups 1 and 2) who remained prepubertal throughout the treatment had a good clinical outcome after 6 to 24 months of GH therapy, with an increased linear growth velocity in comparison with the pretreatment value ($P < .001$ for height and HV; $\Delta\text{HA}/\Delta\text{CA}$ ratio > 1) and a better statistical prognosis, demonstrated both by a $\Delta\text{HA}/\Delta\text{BA}$ ratio greater than 1 and by a higher predicted adult height after the treatment ($P < .001$). We found no correlation between mean GH concentration and HV during treatment; Costin and Kaufman³⁸ and Chalew et al²¹ also did not find this correlation. Albertsson-Wikland¹⁸ showed an inverse relationship between response to GH therapy and endogenous GH secretion, and Hindmarsh et al⁶⁰ demonstrated an inverse curvilinear relationship between the pretreatment sum of GH pulse amplitude and the SD score for HV during GH therapy.

There was no significant difference in the change in the SD score for height, ΔHA , $\Delta\text{HA}/\Delta\text{CA}$, the SD score for HV, the change in the SD score for HV per year of therapy, or in the gain of predicted adult height after the therapy between subjects with classic GH deficiency (group 1) and nonclassic GH deficiency (group 2).

Recently, the procollagen III level has been demonstrated to increase parallel to growth during GH therapy.¹⁸ If this is confirmed, the study of procollagen III may provide additional means to predict response to GH therapy.⁵¹

Our study has also demonstrated that several hormonal and auxologic measurements correlated differently with the mean GH concentration. The highest correlations were found with spontaneous GH secretion measurements (mean nocturnal GH concentration, mean diurnal GH concentration, mean pulse amplitude, and number of pulses with a GH peak greater than 5 $\mu\text{g/L}$) and with somatomedin C levels.

The mean nocturnal GH concentration was higher than the mean diurnal GH concentration in the 104 examined subjects both considered as a group ($P < .001$) and in the individual cases. Also, in other studies the nocturnal GH

secretion was higher than the diurnal GH secretion, by evaluation both of the mean GH concentration during 12 or 6 hours and of the only GH peak.^{38,37,38,52,53}

Since a high correlation has been demonstrated between 24-hour and 12-hour spontaneous GH secretion measurements, an interesting issue in the clinical setting is the chance to use the mean nocturnal or diurnal GH concentration as a reliable substitute for the mean GH concentration, halving the duration of the examination. Both Radke et al⁵² and Richards et al⁵³ have shown a significant correlation between mean GH concentration and shorter periods of time. Diurnal GH secretion has not been considered to be as reliable as nocturnal GH secretion in the assessment of spontaneous hormonal secretion, because, as we have shown, diurnal GH secretion is lower than nocturnal GH secretion.^{24,54-56} To confirm the higher reliability of the mean nocturnal GH concentration, we compared the mean GH concentration with both the mean nocturnal and diurnal GH concentration, evaluating the sensitivity and specificity over a 12-hour period on the basis of the cutoff values (3.66 $\mu\text{g/L}$ for nocturnal and 2.33 $\mu\text{g/L}$ for diurnal GH concentration) calculated by the correlation equations that correspond to the conventional value of 3 $\mu\text{g/L}$ for the mean GH concentration. Our data have demonstrated that both the specificity and sensitivity of mean nocturnal GH concentration were higher than those of mean diurnal GH concentration. In any case, it is evident, as Bercu et al³² have pointed out, that the shorter the period of GH evaluation (12 or even 6 hours vs 24 hours), the less sensitive the result, due to the presence of a considerable overlap in GH levels between subjects with levels higher or lower than the cutoff value.

We found a correlation between mean GH concentration and basal somatomedin C levels ($r = .794$). This finding is in agreement with the data of Costin and Kaufman³⁸ in prepubertal children, of Bercu et al,^{32,35} and of Rose et al,³⁸ but not with those of Rochiccioli.⁵⁷ In our study, somatomedin C levels of subjects with nonclassic GH deficiency were higher than those of subjects with classic GH deficiency ($P < .002$) and lower than those of short normal children ($P < .001$). Furthermore, we also found a statistical difference between children

with nonclassic GH deficiency and short normal children ($P < .001$). Nevertheless, the usefulness of evaluation of somatomedin C to separate short children with a low spontaneous secretion of GH from short normal children is limited, because, as for auxologic features, a significant overlap occurs, as others have demonstrated.^{32,38,43,48,58} In fact, 12 (29%) of the 41 children with a mean GH concentration lower than 3 $\mu\text{g/L}$ had a somatomedin C level above 500 IU/L (all in group 2), while in group 3, 12 (19%) of 63 subjects had a somatomedin C value below 500 IU/L. Rochiccioli⁵⁷ showed 26% false-positive and 30% false-negative results in two similar groups. Finally, our study has shown a correlation between somatomedin C concentration and auxologic features (height, HV, BA/CA ratio, and CA), as Cacciari et al,⁵⁸ Costin and Kauffman,³³ and Rayner et al⁶⁰ demonstrated for BA, HV, and CA. On the other hand, Spiliotis et al⁶⁰ did not show a correlation between basal somatomedin C concentration and growth velocity.

In summary, our study has demonstrated that short children with a normal GH response to provocative testing, a mean GH concentration lower than 3 $\mu\text{g/L}$, and pathologic auxologic features (nonclassic GH deficiency) have shown a good outcome in response to GH therapy given for 6 to 24 months. Therefore, we suggest that, in addition to clinical criteria, 24-hour spontaneous GH evaluation is a useful diagnostic procedure in identifying short children who may benefit from GH therapy. Furthermore, 24-hour spontaneous secretion of GH has been shown to be reduced in several but not all short children with pathologic auxologic features, regardless of GH responses to provocative stimuli. Therefore, the occurrence of pathologic auxologic features alone, although very important in considering GH treatment, is not a sufficient criterion to justify treating a short child with GH. The 24-hour GH evaluation also correlated with other spontaneous GH measurements and somatomedin C levels, even if these data alone were not able to indicate which subjects had a low mean GH concentration.

The selection for GH treatment of short children who do not fulfill the rigid criteria of classic GH deficiency must be performed only by experienced pediatric

ric endocrinologists, who are the most qualified physicians to investigate carefully such patients. In any case, further studies on a larger number of children treated for a longer period are necessary to reach definitive conclusions about the efficacy and safety of GH therapy in short children without classic GH deficiency.

Circumstances Surrounding the Deaths of Children due to Asthma

A Case-Control Study

Bruce D. Miller, MD, Robert C. Strunk, MD

• Features of the courses in 12 children who died of an acute attack of asthma were compared with those in 12 children of comparable age and sex who had a life-threatening attack of asthma but survived. Information obtained by structured interviews with the families and physicians and from the medical records was used to characterize (1) the patient, family, severity, and treatment of asthma primarily in the 6 months before the attack and (2) medical circumstances and patient characteristics present on the day of and/or during the acute episode. Patients in the study (mean age, 14.1 years) and controls (mean age, 13.8 years) were in early to late adolescence, had similar long-term medication use histories and an overall rating of the severity of asthma. For the analysis of the information concerning the 6 months before the attacks, the study patients had a greater frequency of respira-

tory failure requiring intubation, a decrease in steroid use in the month before the attack, history of family disturbance, abnormal reaction to separation or loss, and expressed hopelessness and despair. For the period more immediately surrounding the acute attack, study patients more often had attacks starting during sleep, but less frequently experienced vomiting during the course of the attacks. Treatment of the attack by the parents was poor (primarily because of delays) in 7 of the 12 children who died, but was also a factor in 6 of the 12 controls. Our data suggest that certain characteristics of asthmatic children may place them at greater risk for death due to their asthma. In addition, we postulate that there may be inherent differences in the mechanisms of the acute attacks between the children who died and those who survived.

(AJDC. 1989;143:1294-1299)

Death due to asthma can occur suddenly^{1,2} or after a prolonged attack that has not been treated optimally.^{3,4} Since the 1960s most deaths have occurred outside of hospitals,^{2,3,6,8} although some continue to occur during hospitalization for asthma.^{7,8} Thorough reviews of cases in the United Kingdom and New Zealand have identified potentially avoidable factors contributing to deaths in a large percentage of cases.

Accepted for publication March 20, 1989.

Reprint requests to Department of Pediatrics, Washington University School of Medicine, 400 S Kingshighway Blvd, St Louis, MO 63110 (Dr Strunk).

This was true both for deaths outside of the hospital^{3,9} and in the hospital.⁸ Issues most often cited were poor utilization of corticosteroids and bronchodilator drugs, poor cooperation of the patient with the management of the asthma, failure to recognize the severity of the attack by patients, relatives, and physicians associated with delays in starting appropriate treatment, and inadequate responses of medical services to emergency calls.^{6,9,10}

Circumstances surrounding the deaths due to asthma were first investigated by Fraser et al,¹¹ who focused on bronchodilator and corticosteroid therapy. Excessive inhalation of bronchodilators was thought to have contributed to death in 37% of the patients, primarily by delaying medical advice. In 1984, Johnson et al⁸ found four sets of circumstances in the fatal attack contributing

to deaths: patient failure to recognize severity of the attack, rapid progression in attack severity, misjudgment in management, and delay from many causes. In 1987, Rea et al¹⁰ found many of these same factors. They also noted that some of those who died were unusually fearful or anxious, and some had premonitions of death 1 or 2 days before the event. Finally, the British Thoracic Society¹² has concluded that allergy may play a role in the deaths of some patients. None of the studies concerning the circumstances surrounding death due to asthma was case controlled.

The purpose of our study was to compare the life circumstances and course of events in children who died of an acute asthma episode with those in children who suffered a life-threatening attack of asthma but survived.

PATIENTS AND METHODS

Patients

All subjects were known to have asthma as defined by the American Thoracic Society.¹³ Subjects were identified by physicians primarily in response to a letter sent by the investigators to all former fellows of both the Departments of Pediatrics and Internal Medicine at the National Jewish Center for Immunology and Respiratory Medicine, Denver, Colo. In some cases, the investigators were contacted spontaneously because of their known interest in the problem of asthma mortality.

The cases of 12 children who had died during an acute attack of asthma were referred and utilized for the study. All were judged to have died of acute asthma by both their physicians and the local coroner. One patient died during a hospitalization for increasing asthma, and the rest died at home before resuscitation could be started, during resuscitation at home, or en route to an hospital emergency department. Controls had sur-

vived a "life-threatening" episode of asthma, defined as asthma complicated by respiratory failure, requiring either intubation and ventilation (8 patients) or intravenous isoproterenol (4 patients). When there had been more than one episode of respiratory failure, the most recent was used as the index episode for the study. We selected subjects who had had the index episode within 3 years of the study to assure good recall of the events by parents. The study and control groups were comparable for age and sex.

The study design was approved by the Institutional Review Board at the National Jewish Center for Immunology and Respiratory Medicine. Parents gave verbal consent for their participation in the study. Written consent was obtained to request medical records from their physicians and the hospital(s) involved in the treatment of the index asthma attack.

Interviews of Families and Physicians and Compilation of the Data

Variables for analysis were obtained from three sources: (1) review of literature on asthma mortality that focused on factors important in outcome of severe asthma attacks,^{3,5-7,9,11,12,14} (2) two previous case-control studies on risk factors for asthma mortality,^{15,16} and (3) the investigators' experience in dealing with patients who have died or have had a near death experience from asthma.

The data for this study were obtained by interviews of families and physicians who had cared for the children, from hospital/emergency department records pertaining to the index episode, and from the physician's office records for the 6 months before the episode. The families were each interviewed for 1 to 2 hours, using a semistructured interview, by one of us (B.D.M.). The information was checked for consistency by determining the answer using several different approaches at varied times in the interview. In each case the person responsible for the care of the child at the time of the index episode was interviewed. If this person was different from the usual primary care giver, both individuals were interviewed. These interviews were tape recorded for subsequent reference and further analysis.

The physicians were contacted and interviewed, using a structured interview, by one of us (R.C.S.). Each physician was asked exactly the same set of questions. If the primary physician had not been involved in the acute episode, more than one physician was interviewed to gain a complete database for the patient. Areas covered in the physician interview were similar to those covered in the interview of the parents, except that relatively more emphasis was placed on obtain-

ing information characterizing the patient's asthma, the physician's care—both long-term and in the days preceding the episode—and the events and treatment during the index episode. Hospital/emergency department records and records from the physician's office were examined in most cases to confirm information obtained during the physician interviews.

Immediately after completion of the interviews, each investigator scored each of the variables. A composite summary was then developed by both investigators. The rating was obtained primarily from a single source for some of the variables (indicated below) or from consideration of all three sources. When the rating for an item was different between the sources, the tape of the parent interview,

the written record of the structured physician interview, and the medical records were reviewed again and a judgment was made by consensus of both investigators as to the most accurate data source. If sufficient information was not obtained to score an item, the item was removed from the analysis for the patient.

Asthma, Treatment, and Capabilities of the Child and Family

The variables that were analyzed are summarized in Table 1. The period 6 months before the episode was emphasized. Six variables were used to assess the physiologic status of the patient before the index episode. Asthma severity was assessed by parent and physician interviews and office

Table 1.—Information Characterizing the Patient, Family and Severity and Treatment of the Asthma Before the Attack

Variable	No. of Patients With Variable		P*
	Study Patients	Control Patients	
Physiologic			
Severe asthma	8	5	NS
History of respiratory failure requiring ventilation†	10	3	.006
Decrease in steroid dosage >50% in month before attack†	6	1	.034
Use of inhaled steroids†	5	8	NS
Fatigue	6	10	NS
Unstable asthma for more than 3 days before final attack	4	6	NS
Psychologic			
Family dysfunction†	7	2	.045
Reaction to separation or loss†	10	2	.002
Wheezing with stress†	6	5	NS
Disregard of perceived asthma symptoms†	8	8	NS
Patient-parent conflict†	4	3	NS
Patient-physician conflict†	3	1	NS
Parent-physician conflict†	1	0	NS
Manipulative use of asthma†	0	1	NS
Emotional disturbance†	1	1	NS
Depression†	2	3	NS
Life stressors	4.6	2.7	NS
Hopelessness/despair within 1 month before attack	8	3	.05
Quality of asthma care			
Poor self-care†	7	8	NS
Patient-parent factors adversely affecting care	4	5	NS
Physician factors adversely affecting care	5	3	NS

*P>.10 for values that were not significant (NS).

†These variables were analyzed with a one-tailed test (all others were analyzed with a two-tailed test). These 14 variables have been described previously as distinguishing between children who died of asthma from patients matched for age and overall severity of asthma but known to be alive.¹⁵ They were modified slightly from the previous descriptions to emphasize observations made by the parents and physicians in the 6 months before the index episode (see "Patients and Methods" section). The remaining variables are defined in the "Patients and Methods" section.

records, which included presence of significant asthma symptoms at least once a week for the previous year (primarily from parent report), more than two hospitalizations for asthma in the previous year, more than four emergency department visits in the previous year (parent and physician reports and records), use of oral corticosteroids at least every other day throughout the previous year (primarily from office records), history of rapidly progressing attacks (parent and physician reports), and episodes of loss of consciousness with asthma attacks (parent and physician reports). Presence of three or more of the six criteria defined severe asthma.

History of respiratory failure requiring ventilation was obtained primarily from the physician (no patient had a history of hypoxic seizures with acute asthma attacks). Steroid reduction was defined as a decrease in oral steroid doses by more than 50% within the month before the index episode (office records). Administration of inhaled steroids occurred in the month before the episode (office records). Fatigue or exhaustion were rated when the parents stated that the child had been excessively fatigued within 2 days before the attack. Unstable asthma for more than 3 days before the attack was rated by evidence for increased asthma symptoms in the week before the attack; the information was gained either from the physician record or parent observation of the child's course (the parents frequently had been aware of instability but had not contacted the physician). The precipitating factors for the asthma had not been uniformly evaluated by the physicians; thus, the basis for the severity of the asthma was not evaluated.

Twelve variables assessed the psychologic status of the index and control subjects; ratings were made on the basis of historical report from the parent, care giver, and treating physician. Ratings were made by one of us (B.D.M.) based on the following guidelines. Family dysfunction was rated on the basis of a number of issues, such as the presence of marital discord, lack of emotional support of the child by one or more parent/care giver, presence of parental drug or alcohol abuse, financial instability, lack of consistent support for medical treatment, and lack of extrafamilial psychosocial support systems. Reaction to separation or loss was rated if the child frequently had developmentally inappropriate responses to brief separations from a parent or caregiver (eg, problems with going to school, staying with a babysitter, or enduring other brief parental absences), or if the child had suffered a significant loss within the 6 months before the attack (eg, death of a parent or sibling, loss through divorce or desertion).

Wheezing with stress was rated when the parents and physician considered emotional

stress a frequent precipitating factor for acute asthma episodes and reported that as a problem. Disregard of perceived asthma symptoms were scored if the patient reportedly took no action in response to recognized asthma symptoms. Examples of such behavior included not stopping exercise after clear wheezing had started or failing to self-medicate according to protocol when symptoms warranted. At least two clear instances of such behavior in the 6 months before the event noted by either parent or physician constituted a positive score. Patient-parent conflict, patient-physician conflict, and parent-physician conflict were rated as positive if conflict was reported and corroborated either by the parents and/or physician in any of the three categories; conflict was defined as an ongoing problematic relationship engendering emotional discord consisting of disagreement, frustration, and dissatisfaction. This conflict had to be ongoing throughout the 6 months preceding the index episode. Manipulative use of asthma was rated if the child reportedly used asthma symptoms for secondary gain, eg, to avoid unpleasant tasks, to place pressure on others to respond to the child's wishes, or to seek attention; problems reported in this domain and at least two specific instances of such behavior in the 6 months preceding the index episode constituted a positive score.

Emotional disturbance was rated if the child had been referred for psychiatric treatment within the 6-month period before the event, or if the child appeared to have been experiencing problematic functioning, using guidelines set forth in the Child Global Assessment Scale.¹⁷ Depression was rated on the basis of reported clinical symptoms using the Children's Depression Rating Scale-Revised¹⁸ as a guideline for assessment, or if the child had been treated for depression within 6 months of the index episode.

Life stressors assessed the presence of stressful situations within 6 months of the events that were thought to have affected asthma symptoms or general functioning. There were 10 specific areas of exploration: geographic relocation, recent loss of a family member, parental separation or divorce, school problems, alcohol or other drug abuse, major social upheaval, involvement with the law, short-term illness/hospitalization of family member, attempted suicide of a friend or family member, or two or more hospitalizations of the child. A score of 0 to 10 was recorded for each patient. The emotional state of hopelessness/despair was scored positive if the child was reported to have expressed feelings of hopelessness, a wish to die, or direct or indirect references to suicide or (patient's own) death within 1 month before the index episode.

Quality of asthma care was assessed by

three variables. Poor self-care was rated when the parents and/or physician stated that there were regular problems with the child's ability to respond in an age-appropriate manner to asthma symptoms and to attend to routine, prophylactic care. Patient-parent factors affecting care adversely were assessed with six factors: a consistent care provider (parent and physician reports), calling the physician within 8 hours after the onset of wheezing "most of the time" (physician), taking the child to the physician within 24 hours after the onset of wheezing if there was no response to the usual treatment "most of the time" (physician), keeping scheduled office visits or calling to reschedule for conflicts (physician), correct use of metered-dose inhalers (parent and physician), and parent admission of noncompliance by the child. Patient-parent factors were judged to be present if two or more of these factors were reported to be deficient.

Physician factors adversely affecting care was assessed by seven factors, all of which were judged during the physician interview or by examining office records. The variables included providing specific instructions to the parents concerning when to call and when to arrange a visit during wheezing episodes, arranging follow-up within 48 hours after hospitalization (either an office visit or telephone call), arranging follow-up within 24 hours after an emergency department visit, scheduling office visits every other month during the 6 months before the episode, conducting spirometry measurements at the time of office visits, arranging follow-up within 2 weeks of reduction of steroid dosage by greater than 50%, and measuring theophylline levels at least once within the 6 months before the episode if doses greater than 20 mg/kg were prescribed. Physician factors were judged to be present if problems occurred in two or more of these areas.

Medical Circumstances and Patient Characteristics Present on the Day of and/or During the Acute Episode

These variables are summarized in Table 2. For the variable attack that began during sleep, the time of day and whether the attack occurred as the patient awoke from sleep (either during the night or with a nap during the day) were assessed by parent history. The rate of progression of the attack was assessed by asking the parents and the physician how fast the patient progressed from the state of health present in the last week until resuscitation or emergency department treatment was started; progression in less than 1 hour was considered rapid.

Treatment of the attack was assessed using four variables: whether immediate treatment was begun once the change in course

Table 2.—Medical Circumstances and Patient Characteristics Present on the Day of and/or During the Acute Asthma Attack

Variable	No. of Patients With Variable		P*
	Study Patients	Control Patients	
Attack began during sleep†	7	2	.045
Rapid progression of attack	9	5	NS
Poor treatment of attack (delays)	7	6	NS
Inadequate steroid use	4	4	NS
Inadequate assessment			
By patient or parent	6	6	NS
By physician	1	0	NS
Vomiting	1‡	8	.01
Response time, min	10	15	NS
Poor emergency care during final attack	3	0	NS

* $P > .10$ for values that were not significant (NS).

†Attack began during the night did not distinguish study patients from controls ($n = 7$ in study patients; $n = 4$ in controls; $P = .30$).

‡This patient vomited and then aspirated the vomitus.

was noted, whether this treatment was appropriate (eg, use of inhaled β_2 -agonists), whether there was a delay in calling for help (a call to physician or emergency squad should have been made as soon as a change in course was apparent), and whether there was an overuse of β_2 -agonists (more than 12 nebulizer treatments in the final 24 hours). In most cases, the physician had not been involved in the care within the last 24 hours. Therefore, parent report was used primarily. Initial history in emergency department records were used when complete. Poor treatment was scored if two or more of these variables were present.

Inadequate use of steroids in the final course was scored if there was sufficient cause for their use in time for them to be started, but they were not started or increased from their usual long-term dosage. Sufficient cause for using steroids included scenarios such as being seen in the emergency department within 1 week of the episode with increased asthma that did not respond to the treatment prescribed, having increased asthma symptoms during a hospitalization, having increasingly more severe asthma for at least 24 hours, and using increasingly more β_2 -agonist by inhalation for at least 24 hours without affecting the course.

Inadequate assessment of the severity of the attack by the patient or parent was scored when there appeared to the investigators that there was adequate reason for concern about the progress of the asthma symptoms but no call was made to the physician. Inadequate assessment by the physician was scored when the severity of the attack was not understood and adequate care was not administered (eg, the physician was aware of

frequent use of inhaled β_2 -agonists, but did not initiate steroid therapy when response to bronchodilators was inadequate). Vomiting was scored when it occurred during the period of rapid progression of symptoms before the final loss of consciousness or intubation attempt(s).

Response time in minutes was considered from the call to the emergency department by the parents, or getting into the car to travel to the emergency department, until the initiation of care. Poor emergency care during the final episode was scored when emergency squads did not have epinephrine or oxygen available, or when extreme disorganization of the resuscitation attempt interfered with intubation and/or administration of intravenous fluids.

Analysis of Data

Each variable or variable grouping was studied independently to determine possible differences between the study patients and controls; 2×2 contingency table analysis (Fisher's Exact Test) was used for present/absent data, and Wilcoxon's two-sample test was used for noninterval data. When the direction of a result had been described in previous studies, a one-tailed test was used. All other results were examined using a two-tailed test.

RESULTS

Asthma, Treatment, and Capabilities of the Child and Family

Study patients and controls were in early to late adolescence. Patients studied included 8 boys and 4 girls with a mean age of 14.1 years (range, 10 to 18

years); control patients included 9 boys and 3 girls with a mean age of 13.8 years (range, 11 to 17 years). Most of the episodes occurred during the months of May through June or September through October (9 in the study group and 8 in the control group).

Overall severity of asthma was similar in the two groups. The medications used for a long period were similar in the two groups. All patients in both groups had used oral steroids at some time. Five in the study patients and six controls had used oral steroids at least every other day in the year before the attack. Nine of the study patients and 11 of the controls used theophylline (anhydrous), 11 in each group used inhaled β -adrenergic agents by air compressor, and 7 in the study group and 11 of the controls used inhaled β -adrenergic agents by a metered-dose inhaler. The total amount of medication required for control of asthma was also similar in the two groups: number of medications for study patients was a median of 6 with a range of 1 to 10 compared with 5 (range, 3 to 6) for the controls; total number of doses of asthma medications in a 24-hour period for study patients was a median of 11 with a range of 1 to 21 compared with 11 (range, 6 to 15) for the controls.

Two physiologic variables listed in Table 1 distinguished between the two groups: history of respiratory failure requiring intubation and reduction of steroids by more than 50% in the month before the event. The remaining physiologic variables—use of inhaled steroids, fatigue, and unstable asthma in the week before the final attack—were present in approximately 50% of each group and did not distinguish between the two groups.

Three psychological variables distinguished between the two groups (Table 1): presence of family dysfunction, history of reactions to separation or loss, and hopelessness/despair in the month before the attack. The remaining variables did not distinguish between the groups. Two variables were present in many of both study patients and controls: wheezing with stress and disregard of perceived asthma symptoms. Seven variables were present in a minority of both study patients and controls: patient-parent conflict, patient-

physician conflict, parent-physician conflict, manipulative use of asthma, emotional disturbance, depression, and life stressors. None of the variables reflecting the quality of care of the asthma distinguished between groups.

Medical Circumstances and Patient Characteristics Present on the Day of and/or During the Acute Episode

Two variables distinguished the study cases from the controls: attacks beginning during sleep and vomiting during the attack. Rapid progression of the attack, inadequate assessment by patient or parent, and poor treatment of the attack were prominent in both study patients and controls and did not distinguish one group from the other. While rapid progression of the attack (within 1 hour) did not distinguish study patients from controls, four of the study patients had such rapid progression that the child was moribund by the time resuscitative efforts were initiated. In these four patients there had been no delay in the parent seeking help or in arrival of the emergency squad. Poor treatment was scored in seven study patients and six controls (Table 1), at least in part because there had been delays in calling for help. Inadequate steroid use, inadequate assessment by the physician, or poor quality of care during the final episode were not frequently present in either group.

COMMENT

The results of our study identified differences between children who died during an acute attack of asthma and those who suffered a life-threatening attack but survived. Asthmatics who died had severe disease (history of respiratory failure), periods of medical instability (reductions in steroid therapy), and significant psychosocial problems (increased sensitivity or extreme reactions to separation or loss, a history of family turmoil, and expressed hopelessness or despair). These findings may have been associated with death due to asthma because of the inability of the patients and/or families to react appropriately to rapid changes in the course of severe asthma. Failure to assess the severity of the asthma in an objective fashion and other components of physician care are mentioned frequently as

factors associated with asthma deaths, but were not different between our study and control groups.

Increased sensitivity or extreme reactions to separation or loss and a history of family turmoil have been identified in a number of other studies,^{9,16,19-21} where they were considered traits characterizing the patient/family during some (often unspecified) period preceding the asthma death. However, these psychosocial areas had not been identified previously as active problems in the months immediately preceding death. Emotional disturbance and depression have also been noted as features characteristic of patients who have died of asthma,^{15,16,19,22-25} but neither variable was discriminating in our study. Our results may be related to the relatively stricter definitions used for these conditions compared with those in previous studies; we used psychometric scales and/or an outside professional diagnosis to make a positive rating, and the condition had to be active during the 6 months before death. Hopelessness/despair did discriminate between our two groups. This emotional state is a frequent finding in patients with depression or other forms of emotional disturbance, although hopelessness/despair alone is not sufficient to make a diagnosis of depression. Hopelessness is a discrete emotional state that can be identified at least transiently in many patients suffering from chronic illness, in persons who have suffered a severe physical insult, or in persons who have experienced an important loss.

For the period in and around the time of the acute attacks, nine variables were considered, but only attacks beginning during sleep and vomiting during the attack showed a statistical difference between the two groups (Table 2). Attacks occurring during sleep were considered separately from attacks at night because the physiologic definition of sleep is different from the circadian rhythm of day-night cycles. One such difference is the relative shift to a cholinergic predominance in the central and peripheral nervous systems that occurs during sleep.²⁶ This shift is independent of the circadian rhythm of night and day cycles. Such a neural shift during sleep could increase reactivity of the airways to an asthma trigger. These neurally

mediated changes could explain the suddenness and irreversibility of attacks that begin during sleep. The four study children who experienced sudden collapse after arousal from sleep died as they were attempting to administer some self-treatment for asthma or before help could be summoned. The emotional state of hopelessness/despair is also known to be associated with central and peripheral disturbances in the autonomic nervous system indicative of a relative cholinergic dominance²⁷⁻³¹ and could synergize with the physiologic changes occurring during sleep, with both contributing to a rapid progression and irreversibility of symptoms.³²⁻³⁴

Patients who survived their severe attack were more likely to have vomited during the attack. Before the index attacks, patients in both groups had had vomiting with severe asthma. Vomiting with the previous attacks was almost always described as "bringing about relief of symptoms of asthma almost immediately." The reason(s) that vomiting did not occur during the episodes that preceded the deaths is not known. Although the clinical phenomenon of vomiting producing relief of an asthma attack is well documented,²² no empirical studies have confirmed a mechanism; the flushing, sweating, tachycardia, and tachypnea that follow extreme retching and vomiting suggest that neural pathways may be involved. Vomiting was not always beneficial, however. In one study case of a 10-year-old boy, vomiting occurred after the child had become semiconscious and was receiving cardiopulmonary resuscitation. He aspirated vomitus and apparently suffocated as a result. This child was reported to have vomited during his only other severe asthma episode with consequent immediate relief of symptoms.

Controls were selected for severity of the single asthma episode. They also had an overall severity that was similar to the children who died, as indicated by the overall severity score (Table 1) and the similarities between medication use in the two groups. It is possible that the two groups might have been distinguished from each other if additional studies, such as methacholine reactivity, could have been done. It is also possible that individuals in the two groups

may have had different sensitivities to adverse side effects of the medications used; however, there is no indication that types of medications or the complexity of the medical regimens contributed to the deaths. Neither quality of care given by the parents or the physicians nor the presence of life stressors distinguished between the groups (Table 1). Index episodes occurred most frequently during either spring or fall months in both groups. These periods coincide with periods of the highest prevalence of airborne allergens and may reflect a role for allergy in the episodes for both groups of children.

The need for adequate emergency treatment early in the course of an acute asthma attack is clear. Problems with delays were apparent in many of the study patients, but also in many of the controls. Poor care by the responding paramedic units occurred only in study patients for whom there had been delays in calling the squad. The quality of care may have been affected by the catastrophic nature of the situation at the time of arrival of the squad. While rapid and precise care of emergent asthma by paramedic squads is essential, the apparent misjudgment of the parents in delaying the call for help remains a primary concern.

In summary, the children who died of asthma and were studied in this report differed in the 6 months before their deaths than children who had a severe attack of asthma but survived. However, the circumstances immediately before and during a fatal episode may be the most important issues. Neural instability may be important in producing differences in the course of a severe attack that can lead to a fatality. The role of the factors apparent in the 6 months preceding the attacks in producing the rapid onset and often irreversible bron-

chospasm is unclear and requires further investigation.

Clinical Trial of Single-Dose Intravenous Gamma Globulin in Acute Kawasaki Disease

Preliminary Report

Mary Allen Engle, MD; Nunzia S. Fatica, MD; James B. Bussel, MD;
John E. O'Loughlin, MD; Michael S. Snyder, MD; Martin L. Lesser, PhD

• Gamma globulin administered in a single dose of 1 g/kg of body weight intravenously caused prompt clinical improvement in 27 of 32 consecutive children with Kawasaki disease treated by the 12th day of illness. Response was equally good for the 20 children treated in the first week and the 12 treated in the second week. Fever and clinical signs abated within the first day after treatment, the mean white blood cell count normalized by 48 hours, and the sedimentation rate continued to be elevated for about 2 weeks, while the platelet count rose during the first 2 weeks after treatment and returned to normal approximately 1 month after treatment. Five children with incomplete relief needed more than the single dose before resolution of signs and symptoms occurred. Coronary aneurysms in 2 patients before treatment regressed by 2 weeks. No patient developed coronary aneurysms. No child had sequelae of Kawasaki disease at a follow-up of 2 to 31 months. We believe that although this was a one-arm, uncontrolled pilot study, the results suggest that this protocol provides a safe, flexible, and effective treatment for acute Kawasaki disease.

(AJDC. 1989;143:1300-1304)

Kawasaki disease (KD) is complicated by a 20% to 25% incidence of coronary aneurysms when children are

treated with aspirin alone.^{1,4} A multicenter, randomized, controlled trial of intravenous gamma globulin (400 mg/kg of body weight for 4 days) with aspirin vs aspirin alone demonstrated in August 1986 an unequivocal reduction in incidence of coronary artery abnormalities as well as prompt resolution of clinical and laboratory abnormalities in KD in the group treated with gamma globulin and aspirin.⁵ Others reported similarly encouraging results.^{6,7} We postulated that a large dose of gamma globulin in 1 day of treatment might be as effective in preventing coronary abnormalities and in terminating clinical illness. If so, such a regimen could provide an economic as well as a health benefit. Therefore, in November 1986, we began a pilot study in consecutive children in the acute febrile stage of KD to administer gamma globulin in a single dose of 1 gm/kg, which could be repeated in 48 to 72 hours if needed for relief of symptoms and signs.

PATIENTS AND METHODS

The treatment protocol in our feasibility study used a single dose of 1 g/kg^{8,9} of gamma globulin plus 100 mg/kg of aspirin until the patients were afebrile for 1 day. Each child who met the criteria for diagnosis¹⁰ and who came to us within 14 days of the onset of illness entered the study. The first day of fever was taken to be the first day of disease. Our pilot study was conducted as an open-label, uncontrolled, one-arm clinical trial as opposed to a controlled, randomized trial for two reasons. First, we wanted to determine the safety and efficacy of this dosage as quickly as possible. Second, a controlled, randomized trial would have required several hundred patients to demonstrate a 75% decrease in the failure rate at 2 weeks found in the controlled study⁵ of 8% down to 2%. That was not possible.

We chose 1 g/kg rather than a lower or higher dose because it was the largest dose in 1 day for which considerable experience had been accumulated that demonstrated safety.^{8,9} We were concerned that a higher dose than this might overload the circulatory system in these patients with myocarditis.

Because our experience with 110 children with KD between 1980 and 1986 had demonstrated no difference in the incidence of coronary abnormalities between those patients receiving high-, medium-, or low-dose aspirin⁴, we limited the use of high-dose aspirin to the period of fever plus 24 hours. We then reduced it to a low, platelet-inhibiting dose for 2 months.

The Institutional Committee on Human Rights in Research gave permission to undertake this study. All parents signed informed consent for their children.

Patient Assessment and Laboratory Evaluation

On patient admission, we confirmed the diagnosis of KD¹⁰ and obtained electrocardiograms, M-mode and two-dimensional Doppler echocardiograms, chest roentgenograms, complete blood cell counts with platelet count and erythrocyte sedimentation rate, blood chemistry values, and urinalysis results. We repeated the blood studies, electrocardiograms, and echocardiograms once or twice weekly in the first 2 weeks after treatment, at 1 and 2 months, 6 and 12 months, and 2 years after onset. If coronary involvement has not been demonstrated by 2 months, it is highly unlikely that aneurysms will develop thereafter.

Two experienced echocardiographers, nonblinded collaborating investigators, interpreted and agreed on findings of the echocardiograms, using generally accepted criteria,¹¹⁻¹⁸ as in previous reports from our laboratory for studies on KD^{4,14} and as in the Newburger et al⁵ controlled study. Evidence of pericardial effusion, myocardial dysfunction, and valvular regurgitation was sought. With the use of two-dimensional echocar-

diography, we evaluated the proximal portions of the left main coronary, left anterior descending, and circumflex coronary arteries, and we viewed the origin of the right coronary artery and its course in the atrioventricular groove. The presence of dilatation or aneurysm was interpreted as an abnormality.

Intravenous Gamma Globulin Treatment

The patients received intravenous gamma globulin as a lyophilized product reconstituted to a 5% to 6% solution and given over a 6- to 8-hour period. The gamma globulin preparations were those in regular use in our hospital: Gammagard (Hyland Therapeutics Division, Travenol Laboratories Inc, Glendale, Calif) and Sandoglobulin (Swiss Red Cross, Berne, Switzerland; Sandoz Pharmaceuticals Corp, East Hanover, NJ, distributor).^{15,16}

Aspirin

We gave 100 mg/kg of aspirin daily in four doses until fever had abated for 24 hours. Then we reduced the aspirin to one fourth to one whole baby aspirin (82 mg) daily for 2 months for its effect on inhibiting platelet aggregation.

Methods

Fisher's Exact Test was used to compare the rates of coronary abnormalities at 2 weeks and 2 months in our study with that of Newburger et al.⁵ Among the three treatment groups, when a significant difference ($P < .05$) was found, pairwise comparisons of each group were made using Fisher's Exact Test with a Bonferroni adjustment to account for multiple comparisons.

RESULTS

Patient Characteristics

From November 1986 through March 1989, we treated 32 consecutive patients with typical KD,¹⁰ 20 by the seventh day and 12 between the eighth and 12th days. Twenty-three children had the onset of illness in the 5 months between April and August. Ages ranged from 8 months to 13 years (mean, 3.5 years), and 7 were less than 1 year of age. Eighteen were male. Racial or ethnic distribution included 11 black, 9 white, 8 Asian, and 4 Hispanic children.

Clinical Features

In addition to the usual signs (sustained fever, rash, changes in mucous membranes and tongue, edema and erythema of hands and feet, cervical ad-

enopathy, conjunctivitis, and irritability), seven patients each had arthralgia and diarrhea, three complained of abdominal pain, one had hepatitis and hydrops of the gallbladder, and one had orchitis.

Risk Factors for Coronary Artery Involvement

Using the risk factors that were statistically significant in our previous report on 25 patients with coronary artery disease among 110 consecutive patients with KD treated by us with aspirin alone between January 1980 and August 1986,⁴ we found one or more risk factors in all but 1 patient. Since all children were treated by day 12 of illness, the single most significant risk factor (fever for 2 weeks or more) did not apply. Fourteen children had an erythrocyte sedimentation rate that exceeded 100 mm/h, 10 of them before they were given intravenous gamma globulin, but only 6 had such a high erythrocyte sedimentation rate in the first week. Thirteen patients had pericardial effusion, evident in each on admission. Eleven had a platelet count greater than $1 \times 10^{12}/L$ but only 2 children, both treated on day 12, had such a high count before administration of intravenous gamma globulin.

Response of Clinical Features

Twenty-seven children experienced prompt and dramatic clinical improvement that continued through discharge and follow-up. The mean highest temperature within the 24 hours before intravenous gamma globulin administration was $39.4^{\circ}C$ and $37.5^{\circ}C$ within 24 hours after the dose was administered. Fever did not return. There was no difference in response between the 18 children treated in the first week ($39.5^{\circ}C$ down to $37.6^{\circ}C$) and the 9 treated in the second week ($39.2^{\circ}C$ down to $37.4^{\circ}C$). They received the single dose of intravenous gamma globulin.

Five children received a dose of more than 1 g/kg of intravenous gamma globulin. One, a 2½-year-old boy, was transferred to us after failure to respond to two doses of 400 mg/kg of intravenous gamma globulin on the ninth and 10th days of illness. Clinical features cleared after 24 to 48 hours of 1 dose of 1 g/kg of intravenous gamma globulin. A second

child, aged 4½ years, failed to show improvement after a 4-day course of 400 mg/kg of intravenous gamma globulin on the fifth through ninth days of illness. On admission to The New York Hospital, New York, NY, on day 10, her temperature was $39.4^{\circ}C$, and she fulfilled all criteria for KD. She received 1 g/kg of intravenous gamma globulin on day 11 and showed improvement but remained febrile, with a temperature of $38.6^{\circ}C$. Therefore, she received a second dose of 1 g/kg. Signs and symptoms completely abated. Three other children, one with a coronary aneurysm before intravenous gamma globulin administration, had incomplete relief after the single dose and received a second dose 48 to 72 hours later, followed by further improvement. In these children, the mean high temperatures before and after the first dose were $39.3^{\circ}C$ and $38.4^{\circ}C$, respectively. After the second dose, it was $37.3^{\circ}C$. Two of the five patients who received more than the single dose of intravenous gamma globulin were treated in the first week.

Response of Laboratory Findings

Within 48 hours of administration of the intravenous gamma globulin, the elevated white blood cell count with leftward shift decreased in all but those who were re-treated. Before administration of intravenous gamma globulin, the mean white blood cell count was $18.6 \times 10^9/L$, and 2 days later it was $11.5 \times 10^9/L$. There was no significant difference between those patients treated in the first week ($18.8 \times 10^9/L$ down to $11.5 \times 10^9/L$) and those treated in the second week ($18.5 \times 10^9/L$ down to $7.2 \times 10^9/L$).

Before treatment with intravenous gamma globulin, the mean erythrocyte sedimentation rate was 73.7 mm/h. After 48 hours and at 1 week, the mean erythrocyte sedimentation rate remained elevated (79.4 mm/h and 73.3 mm/h, respectively) before it declined to a mean value of 48.8 mm/h at 2 weeks and 29.8 mm/h at 1 month. The erythrocyte sedimentation rate exceeded 100 mm/h in 14 children. Ten of them, including 3 children who received two doses of intravenous gamma globulin and 6 children treated in the first week, had an erythrocyte sedimentation rate of greater than 100 mm/h before admin-

istration of intravenous gamma globulin.

The mean platelet count was slightly elevated before administration of intravenous gamma globulin to $535 \times 10^9/L$. Children treated in the first week had a lower mean platelet count ($414.4 \times 10^9/L$) than did those treated in the second week ($701.7 \times 10^9/L$) ($P < .001$). The count was higher than normal in only 9 of 20 children treated in the first week, yet it was higher than normal in 11 of 12 children treated in the second week ($P < .001$). Thrombocytosis greater than $1 \times 10^9/L$ occurred before administration of intravenous gamma globulin in only 2 children, both in their 12th day of sickness, and after administration of intravenous gamma globulin in 9 more. In general, the count rose through the second and third weeks and normalized by 1 month after treatment.

Thirteen children had abnormal electrocardiograms on admission with changes in ST segments and T waves (12 children) and with prolonged PR interval (1 child). Tracings were normal by 1 week, but during convalescence the T waves in leads V5 and V6 became tall and peaked¹⁵ in 18 patients, 9 of whom had had a normal electrocardiogram before treatment.

Effect on Coronary Arteries

No child developed abnormalities of the coronary arteries after the intravenous gamma globulin treatment was begun. The follow-up has been from 2 to 31 months, with 15 patients under observation for longer than 1 year. Before treatment on the sixth day of illness, 2 boys had coronary aneurysms, 1 involving the right coronary artery and the other at the origin of the left main coronary artery and at the bifurcation with the left anterior descending artery. Because of persistence of fever, leukocytosis, and symptoms, the first child received a second infusion of 1 g/kg of intravenous gamma globulin 48 hours after the first. In both instances, aneurysms resolved by 2 weeks.

Pericardial Effusions.—Pericardial effusions present in 13 patients at admission (12 in the first week), disappeared by the second week after therapy. No patient developed an effusion after treatment.

Myocardial Abnormality.—In only

one child (treated on day 5) was the ejection fraction before administration of intravenous gamma globulin low (54%) and the left ventricular dimension above normal. On the next day the ejection fraction was 60% and the left ventricle was less enlarged. No patient developed echocardiographic changes of myocardial impairment during the follow-up.

Valvular Regurgitation.—Valvular regurgitation was not found by auscultation or Doppler echocardiography before or after intravenous gamma globulin.

Days of Hospitalization.—The mean New York Hospital stay was 4.4 days, and the median was 4 days. One child was treated as an ambulatory patient. No short-term unfavorable reaction took place in any patient during or soon after infusion of gamma globulin. A 9-year-old boy developed a transient, passive, Coomb's-positive hemolysis caused by an anti-B alloantibody.

Aspirin Therapy.—Because most children were treated with intravenous gamma globulin on the day of admission and were afebrile in 24 hours, only five children received full-dose aspirin therapy for longer than 2 or 3 days.

COMMENT

The primary goal of this clinical trial with a new regimen for intravenous gamma globulin was to prevent the development of coronary abnormalities. We hoped also to terminate signs and symptoms of the illness promptly, thereby shortening hospitalization and decreasing the cost of treatment. The results of this pilot study confirm that intravenous infusion of gamma globulin shortens clinical illness and prevents development of coronary abnormalities in children with KD.^{6,7} The question now concerns the optimal treatment with intravenous gamma globulin—when it should be given, in what dose, and to whom.¹⁶

Pathologic studies by Fujiwara and colleagues¹⁷ of coronary arteries in this disease indicated that aneurysm formation was the extreme manifestation of a vasculitis present in the major coronary arteries even in patients without demonstrated coronary dilatation in the acute stage. If early treatment in the first week could abort this process, it

would seem worthwhile to use a large dose of intravenous gamma globulin as a single dose as soon as the diagnosis is made. Early treatment requires pediatricians to be alert to the possibility of KD in children with sustained fever and rash. We recognize the difficulty in being certain of the diagnosis before the seventh day, since some signs initially may not seem characteristic and because there is no specific diagnostic test. Although previous studies showed that gamma globulin treatment initiated before the 15th day was effective,^{6,7,18} it seems reasonable that, if possible, the treatment should be given in the first week.

This clinical trial addressed the question of dosage. One large dose early rather than four smaller doses over 4 days seemed to us to offer the possibility of quickly and favorably interrupting the sequence of symptoms, signs, and complications while decreasing the total amount of gamma globulin infused and the days of hospitalization. This concept was reinforced by the changes in *in vitro* immune function seen overnight by Leung et al.¹⁹ We selected the dose of 1 g/kg over 6 to 8 hours with the thought that it could be repeated if symptoms and signs did not rapidly improve. The flexibility of this protocol permitted us to design the treatment to match the patient's response. Twenty-seven children responded well to a single dose while five required more than one dose. No coronary artery dilatation or aneurysm developed after intravenous gamma globulin treatment, and two aneurysms, present before treatment on the sixth day, regressed by 2 weeks later. Since aspirin was given in high doses to only five patients for longer than 2 days, we think it contributed little to the favorable outcome.

We compared the results in this pilot study of consecutively treated patients with those of the multicenter, controlled study⁸ that used four daily doses of intravenous gamma globulin for a total of 1.6 g/kg (Table). Both intravenous gamma globulin protocols were significantly better than aspirin alone, and the two regimens with intravenous gamma globulin were not statistically significantly different from each other. There was a small group of patients (8%) in the controlled trial who had coronary ab-

Comparison of Treatment Regimens*			
Regimen	Total No. of Patients/ No. (%) of Patients With Coronary Abnormality		
	Before Treatment	2 wk After Treatment†	7 wk-2 mo After Treatment‡
I	78/4 (5.1)	78/18 (23.1)	79/14 (17.7)
II	75/2 (2.7)	75/6 (8.0)	79/3 (3.8)
III	32/2 (6.3)	32/0 (0.0)	32/0 (0.0)

*I indicates treatment with aspirin alone; II, aspirin plus 400 mg/kg of intravenous gamma globulin; III, aspirin plus 1 g/kg of intravenous gamma globulin.

† $P < .02$ for regimen I vs II, $P < .003$ for regimen I vs III, and not significant for regimen II vs III.

‡ $P < .01$ for regimen I vs II, $P < .01$ for regimen I vs III, and not significant for regimen II vs III.

normalities at 2 weeks and 4% at 7 weeks despite intravenous gamma globulin treatment. Although 6% of our patients had aneurysms before treatment, none did so by 2 weeks or 2 months afterward. The use of a flexible drug strategy has the advantage of allowing a second dose for less responsive patients with persistent fever, irritability, and other signs of illness.

We recognize that a proper comparison requires a controlled, randomized trial. To use historical controls in our own institution, as we did for the 110 children treated in the preceding 6 years with aspirin alone,⁴ has well-known limitations. However, the criteria for diagnosis of the disease and for echocardiographic interpretation were the same and the observers were the same throughout. The regression of aneurysms was more rapid than we had previously experienced.⁴ We believe that our pilot study of single, high-dose intravenous gamma globulin suggests enough potential benefit to warrant further study in a controlled, blinded, randomized clinical trial. Such a trial ideally should contrast with fixed-dose intravenously administered gamma globulin and determine whether aspirin plays any role at all. This will require several hundred patients.

Who should receive intravenous gamma globulin? Can those at greatest risk

be confidently selected? We analyzed risk factors for development of coronary artery abnormalities^{4,20,21} in these 32 patients to see if this would have helped us to select for early treatment in the first 7 days only those 20% to 25% of patients who would be expected to develop that complication. We had found that three laboratory findings were associated with risk: sedimentation rate greater than or equal to 100 mm/h, platelet count greater than or equal to $1 \times 10^{12}/L$, and echocardiographic evidence of pericardial effusion. Although the sedimentation rate was this elevated in 14 children, only 6 children in the first week had a value this high. In no child was the platelet count greater than $1 \times 10^{12}/L$ in the first week. The other sign, pericardial effusion,^{4,21} was present in 13 children, 11 of whom were seen and treated in the first week. These variables do not allow a reliable early selection of patients at high risk for developing coronary artery aneurysms. Therefore, we believe that treatment with intravenous gamma globulin should be given to all children with acute KD.

While we have concentrated on the most common cardiac sequela, the coronary artery disease, it is also true that valvular heart disease in the form of mitral and aortic regurgitation did not occur in this group of patients.

What did it cost to prevent the serious

complications of KD? The cost of one course of 1 g/kg of gamma globulin was less than the cost for the 4-day course of 400 mg/kg daily. Furthermore, the median hospital stay of 4 days was shorter with the single-dose protocol even though five children needed a second course and a longer stay. Therefore, intravenous gamma globulin given in a flexible regimen beginning with a single dose of 1 g/kg may not only prevent development of coronary artery aneurysms but also "pay for itself" by shortening illness and hospitalization. The cost to the child who develops coronary artery disease and to his or her family as well as to society is enormous in comparison to the cost of giving gamma globulin to all children with acute KD.

CONCLUSIONS

We conducted a clinical trial as a pilot study in children with acute KD, using a single dose of 1 g/kg of intravenous gamma globulin. We found it to be effective in 27 of 32 patients. The other 5 patients had an equally good result after a dose that ranged from 1.5 to 3 g/kg. This regimen terminated the signs and symptoms of illness and prevented coronary artery and valvular complications. Despite the limitations of a one-arm, uncontrolled study, we believe that this treatment protocol has both medical and economic benefits and should be further evaluated.

We are grateful for the cooperation of the pediatric cardiology fellows and the pediatric house staff at Cornell University Medical College, New York, NY, in carrying out this protocol. We acknowledge with appreciation the contributions to this study of Kathryn H. Ehlers, MD, and June Robins of the echocardiography laboratory and of Ethel Longo, Rebecca Campbell, Brina Ellis, Denise Simonette, and Lydia Rosario of the graphics laboratory; Sylvia Carnazza, research student; Ginette Lanois, hematology technician; as well as the nursing care provided by Julie Fitzgerald-Pedersen, RN, and Mickey Miceli, RN. We thank Linda Rasoulnejad for assistance in follow-up of patients, Shiela Reams for help with statistics, and Trish Simmons for manuscript preparation.

Book Review

Child Sexual Abuse: A Handbook for Health Care and Legal Professionals, by D. H. Schetky and A. H. Green, 264 pp, \$27.50, New York, NY, Brunner/Mazel Publishers, 1988.

Child Sexual Abuse, A Handbook for Health Care and Legal Professionals is an excellent resource for the professional interested in improving his or her database and skills in caring for sexually abused children. This concise volume, less than 300 pages, is readable and well referenced. As the excerpt below illustrates, the introduction begins with some interesting cultural comments regarding child sexual abuse in general and incest in particular:

Sociological reasons for the [incest] taboo stem from the need to strengthen the tribe through new alliances. This was very simply and eloquently stated to Margaret Mead by an elderly member of the Arapesh of New Guinea, who replied in response to her query about incest, 'What, you would like to marry your sister! Don't you want a brother-in-law? Don't you realize that if you marry another man's sister and another man marries your sister, you will have at least two brothers-in-law while if you marry your own sister you will have none? With whom will you hunt, with whom will you garden, whom will you visit?'

The authors divided their book into these sections: overview, which includes a review of normal psychosexual development and historical perspectives; evaluations; legal issues; and treatment and prevention. At the end is an extensive appendix of references and educational materials with many useful authors' comments.

The clinical evaluation of child sexual abuse discussed in chapter 4 is a succinct but thorough description of what an

appropriate evaluation entails. An adequate and timely evaluation requires considerable skill and knowledge, and the authors clearly outline the pitfalls and milestones involved in completing the task. In view of the demands of this type of evaluation it is clear that practitioners who are unwilling or unable to perform such detailed assessments should be prepared to refer them to individuals who are skilled and experienced in such evaluations.

A good overview of what is involved in the medical evaluation of these patients is covered in chapter 5. Practitioners should consider this chapter a springboard for more study. For example, the authors correctly note that different positions may be used to examine a child who has been sexually abused. However, physicians need to be aware that the same genital structures may have significantly different measurements in different positions. Examiners need experience and training to interpret findings correctly. The chapters that deal with the child and the expert as witnesses are very informative. Finally, the last two chapters, on treatment and prevention, give a good summary of current practice and theory in these areas.

The authors have addressed a complex and difficult subject well, and have compiled a concise and useful body of knowledge. *Child Sexual Abuse* will be of interest to professionals in many disciplines who serve these unfortunate children and their families.

"HOT"

Cool her fever with the brand that offers the most dosage choices

When your patients need fever relief, Children's **TYLENOL**® acetaminophen should be your first choice. **TYLENOL**® offers you more dosage choices than any other acetaminophen brand, so your patients get the right medicine in a form and flavor that's right for every child's needs:

- ☐ Alcohol-free Infants' Drops
- ☐ Alcohol-free Children's Elixir in Cherry and *New Grape* flavors
- ☐ Children's 80 mg Chewables in *both* Grape and Fruit flavors
- ☐ Easy-to-swallow 160 mg Junior Strength Coated Caplets for 6- to 14-year-olds

Remember, **TYLENOL**® is clinically proven as effective an antipyretic as aspirin, with a superior safety profile.^{1,2} And parents can easily find your recommendation, because **TYLENOL**® products are more widely available in food and drug stores than any other brand.³ So next time a little patient is "Hot!" with fever, make your first choice **TYLENOL**® acetaminophen.

Antiviral Drugs in Pediatrics

Henry H. Balfour, Jr, MD, Janet A. Englund, MD

• Pediatricians are made familiar with antiviral drugs and are provided with specific recommendations for treatment of viral diseases. The antiviral drugs in clinical use today are discussed in terms of their doses, routes of administration, mechanisms of action, established and potential efficacies, and toxicities. These drugs include acyclovir, amantadine, trisodium phosphonoformate, ganciclovir, ribavirin, rimantadine, vidarabine, and zidovudine. Biologic response modifiers, such as interferons, are mentioned briefly in their historical context. Future trends in antiviral therapy are anticipated with mention of the most promising candidate compounds currently in preclinical trials.

(AJDC. 1989;143:1307-1316)

Treatment of viral infections was once considered one step removed from witchcraft. Progress in antiviral therapy was impeded by the scarcity of dependable and rapid viral diagnostic techniques coupled with the misconception that all children must endure viral infections because the therapy was worse than the illness. Fortunately, that situation has changed. Due to the recent proliferation of clinical virology laboratories, it is now possible for nearly every physician to obtain laboratory confirmation of a viral diagnosis, and numerous carefully controlled clinical trials have dispelled the myth that the treatment is worse than the disease. Indeed, antiviral therapy should now be an integral part of today's practice of pediatrics. How did that come about, where are we now, and where might we be going in the future?

THE ADVENT OF ANTIVIRAL THERAPY

The difficulty of propagating viruses in the laboratory and the lack of suitable techniques to work with viral genes and their products were the basic reasons for the slow development of antiviral drugs in the 1950s and 1960s. The antiviral effort looked even more feeble when compared with the rapid growth of antibacterial therapy. Despite technical limitations, investigators still were able to make progress in the treatment of viral infections by taking two different approaches: chemotherapeutic and immunologic. The chemotherapeutic approach aims to develop drugs that block specific steps in viral replication. The immunologic approach concentrates on compounds that enhance the host's immune defense against viral infection. Such compounds are called biologic response modifiers because they exert their activity through the host's immune system rather than directly affecting the events of viral infection and replication.

Drugs active against smallpox, known as thiosemicarbazones, represent the first chemotherapeutic agents used successfully to prevent a human viral disease. However, the global eradication of that scourge relegated this early work in antiviral chemoprophylaxis to obscurity. Hamre and colleagues¹ reported in vitro activity for two thiosemicarbazones against vaccinia in embryonated hens' eggs and mice in 1950. A decade later, isatin thiosemicarbazone was shown to protect mice from the intracerebral inoculation of a strain of smallpox.² Three years after that, in 1963, Bauer and colleagues³ demonstrated that a thiosemicarbazone could prevent smallpox in humans. These compounds were tested for antiviral effects simply because they were active against another infectious agent, *Mycobacterium tuberculosis*. Their mechanism of action against pox viruses

was never completely elucidated but appeared to be interference with the production of a late viral structural protein.⁴

A second class of antiviral drugs, the caged carbocyclics, was developed and tested in the 1960s. In 1961, Jackson and his colleagues⁵ provided convincing evidence that amantadine prevented influenza A. Yet, a quarter of a century later, amantadine is still not generally utilized as an effective antiviral compound because of its narrow therapeutic index, limited spectrum of action, and minimal effectiveness unless given during the first few days of illness. Amantadine will be discussed further in the section on influenza.

In the early 1970s, anticancer drugs were reported to be of benefit for treatment of serious viral diseases, but these open-label studies were later refuted. For example, reports that idoxuridine was useful for treatment of herpes encephalitis⁶ and that cytarabine was therapeutic for herpes zoster^{7,8} were ultimately discredited. Idoxuridine did not reduce the amount of virus in brain tissue in patients with herpes encephalitis and was far too toxic for systemic administration.⁹ Immunosuppressed patients given cytarabine for treatment of herpes zoster fared worse than those who received placebo,¹⁰ which underscored the necessity for carefully designed placebo-controlled trials to evaluate antiviral drugs. Such studies were subsequently conducted by Whitley and colleagues,¹¹⁻¹³ whose multicenter, randomized, placebo-controlled trials established the therapeutic efficacy of vidarabine for treatment of serious herpes group viral infections. These exemplary studies became the yardstick against which the utility of subsequent antiviral compounds was measured.

In the 1970s, the interferons emerged as promising biologic response modifiers for treatment of viral infections.¹⁴ Interferons were especially attractive because of their broad spectrum of anti-

viral activity. It is now known that interferons are proteins of at least three distinct types: alpha, beta, and gamma. These proteins, which are coded for by the host, do not act directly on viruses but require the cellular synthesis of both RNA and protein to be active. Once interferon is produced by cells, it is released and functions like a hormone: it binds to specific and nonspecific receptors at the plasma cell membrane, is internalized, and alters cellular enzymatic activities so that production of viral proteins is reduced. Early clinical trials utilized human leukocyte interferon, whereas interferons made from recombinant or purified sources have been recently tested for treatment of a number of unrelated human viral diseases. Unfortunately, an ill-defined mechanism of action and frequent influenzalike side effects have hampered the clinical application of interferons and their inducers.

The past has taught us that specific obstacles need to be overcome to develop clinically useful chemotherapeutic agents or biologic response modifiers. Some of the major hurdles follow:

1. The expression of viral diseases is variable, making carefully designed, randomized, controlled clinical trials mandatory.
2. Clinical and laboratory end points used to determine antiviral effects are not standardized and are often indistinct.
3. The presence or promise of viral vaccines dampens the enthusiasm to develop antiviral therapy.
4. The commercial value of candidate antiviral drugs is questionable, especially if their use benefits only a small group of patients, such as bone marrow allograft recipients.

Despite these obstacles, the era of antiviral therapy has dawned. In this review, we will concentrate on the chemotherapeutic drugs currently in clinical use (Table 1). Antiviral compounds will be discussed in the context of their clinical indications; biologic response modifiers are mentioned briefly where appropriate.

ANTIVIRAL DRUGS: THE PRESENT Herpes Simplex Virus Infections

Substantial advances have been made in this decade against infections caused

by herpes simplex virus types 1 and 2. Indeed, more treatment trials have been designed for herpes simplex virus infections than for any other human viral disease. There are several reasons for this intense scientific scrutiny: herpes simplex virus infections may have serious consequences, particularly in immunocompromised hosts; the virus grows well in many cell culture systems; and herpetic lesions are easily recognized, and, thus, progression to healing can be closely monitored during clinical trials. Nevertheless, some of the most common herpetic infections have not yet been studied in controlled clinical trials, and the optimum dosages of antiviral drugs for other herpes diseases have yet to be established.

Two drugs have been proved effective for treatment of systemic herpes simplex virus infections: vidarabine and acyclovir. Vidarabine, which acts at multiple sites in the viral replicatory cycle, does not require a virus-encoded enzyme to be converted to the active state, vidarabine triphosphate. Vidarabine triphosphate is both a competitive inhibitor of and faulty substrate for viral DNA polymerase; it also inhibits several steps in viral RNA synthesis, including capping of viral messenger RNA.¹⁵ The compound is rapidly degraded by adenosine deaminase to vidarabine hypoxanthine, a derivative with much less antiviral activity than its parent. Because vidarabine is poorly absorbed orally and is relatively insoluble, it must be given intravenously in a relatively large volume of 5% dextrose solution. A disadvantage of vidarabine is its potentially severe central nervous system toxicity.¹⁶

Acyclovir, an acyclic analogue of guanosine, must be phosphorylated to acyclovir triphosphate to exert its antiviral activity.¹⁷ The metabolism of acyclovir to acyclovir monophosphate is accomplished by a virus-specified deoxynucleoside kinase commonly called thymidine kinase (TK). Acyclovir is then further phosphorylated to acyclovir triphosphate by host cell enzymes. Like vidarabine triphosphate, acyclovir triphosphate is both an inhibitor of and a faulty substrate for viral DNA polymerase. Acyclovir triphosphate is also an inhibitor of cellular DNA polymerase, but very little acyclovir triphosphate is

generated in uninfected mammalian cells. Therefore, acyclovir exerts minimal inhibition on cellular alpha-DNA polymerase in uninfected cells, which is the major reason for its low toxicity. However, uncommon adverse effects or sequelae resulting from long-term use of acyclovir in children have not been completely ruled out, because acyclovir has been in clinical use for a relatively short time.

The other antiherpes drugs licensed only as topical ophthalmic preparations are idoxuridine and trifluridine, which are both nucleosides that inhibit viral DNA polymerase. They are effective topically but are too toxic for systemic administration. Both ganciclovir and trisodium phosphonoformate (Foscarnet) are active against herpes simplex viruses *in vitro*, but are not licensed in the United States at the present time for children and cannot be recommended for routine use in herpes infections because acyclovir is less toxic and easier to administer.

Herpes Keratitis.—This is the only viral disease for which we have the luxury of three topical treatment options: idoxuridine, vidarabine, or trifluridine. Acyclovir ophthalmic ointment is available in some countries, but not the United States. When is it appropriate to treat a child with herpes keratitis systemically rather than topically? Systemic therapy is recommended for infants under the age of 1 month or for patients who have a generalized herpetic infection manifested by mucosal and cutaneous lesions. Herpes keratitis occasionally precedes encephalitis, and, therefore, any patient who shows signs of central nervous system dysfunction should be treated systemically.¹⁸

Neonatal Herpes.—This is one of the most devastating viral infections confronting pediatricians. The incidence of neonatal herpes in the United States is about 1 in 8000 live births.¹⁹ Recent controlled clinical studies have suggested that early therapeutic intervention is necessary to minimize morbidity.^{18,20} A trial of vidarabine vs acyclovir did not prove either medication to be clearly superior.²¹ We prefer acyclovir because of its better solubility in intravenous fluids, the availability of an oral formulation, and greater efficacy for treatment of most types of herpetic infec-

Table 1.—Antiviral Drugs in Clinical Use (Excluding Antiretroviral Drugs)*

§This is not a licensed indication or formulation in the United States.

tions. To assure a better outcome for the child, however, our diagnostic skills need to be improved and the optimum dosage of antiviral drugs firmly established. Because treatment of the infant may not be instituted in time to prevent brain damage, the administration of acyclovir to "high-risk" mothers before delivery is being investigated.

Acyclovir appears to be safe and effective in healthy term newborns with normal renal function. Because approximately 80% of acyclovir administered intravenously is eliminated by the kidneys, the dose must be adjusted according to creatinine clearance. Peritoneal dialysis and blood exchange transfusions, unlike hemodialysis, do not remove an appreciable amount of acyclovir.²² If available, acyclovir levels are useful for monitoring therapy in premature infants and infants in renal and/or hepatic failure. Our recommendations for acyclovir dosages in children, including infants and patients with compromised renal function, are given in Table 2.

Herpes Gingivostomatitis.—The typical child with primary herpes gingivostomatitis does not need antiviral treatment. If children are so uncomfort-

able that they stop drinking and require hospitalization for parenteral fluids, it is reasonable to give them intravenous acyclovir. Some pediatricians elect to treat ambulatory patients who have a relatively severe episode of either primary or recurrent oral herpes. In such instances, we recommend oral acyclovir. The only oral acyclovir formulation presently available in the United States is a 200-mg capsule. When treating toddlers, the capsules can be opened and their contents mixed with either applesauce or fruit juice. Domestic licensure of an oral acyclovir suspension (200 mg/5 mL) is pending and, once approved, will make oral administration for young children much easier. Older children often report having a sensory prodrome prior to the eruption of oral herpes. If therapy is elected, it should be instituted as soon as the prodrome is felt and continued until the lesions crust. Long-term suppressive therapy for oral herpes in children is not recommended.

Herpes Whitlow.—Herpes whitlow frequently results when children with oral herpes suck their fingers. If therapy is elected, these patients must be treated with oral or intravenous acyclovir because herpetic whitlow involves

subcutaneous tissues and will not respond to topical acyclovir.²³

Genital Herpes.—Primary genital herpes is often a significant clinical illness that requires either intravenous or oral acyclovir. Pediatricians should consider the possibility of sexual abuse in young patients with genital herpes. Patients should be counseled about the possibility of recurrences. Episodes that are not associated with systemic symptoms and occur infrequently do not need to be treated unless these recurrences are psychologically intolerable. Patients with frequent recurrences (six or more per year) will benefit from suppressive therapy. If suppressive therapy is elected, we recommend that it be discontinued for several months approximately every 6 months to reevaluate its need. Most patients can be weaned off acyclovir after 6 months to 2 years. Although lesions may recur following discontinuation of suppressive therapy, a recent clinical trial has confirmed the adage that "the severity and frequency of recurrences of genital herpes diminish with time."²⁴ Alternatively, early patient-initiated therapy of recurrences at the onset of symptoms may be effective in older children.

Table 2.—Acyclovir Dosage Recommendations for Children*

Indication	Underlying Condition	Route of Administration	Amount per Dose, mg/kg	Frequency of Dose	Duration, d
Herpes simplex virus Neonatal herpes	Term newborn	IV	10	Every 8 h	14-21
	Premature infant	IV	10	Every 8-12 h	14-21
Encephalitis	Otherwise normal	IV	10	Every 8 h	10-14
Mucocutaneous herpes	Immunocompromised or hospitalized for fluids	IV	5	Every 8 h	5-7
Herpes infections in renal failure	CrCl, 0.42-0.83 mL/s	IV	10	Every 8 h	7
	CrCl, 0.17-0.42 mL/s	IV	10	Every 24 h	7
	CrCl, <0.17 and hemodialysis	IV	10	Every 48 h	7
	Continuous peritoneal dialysis	IV	5	Every 24-48 h	7
	Double-volume blood exchange	IV	5	Every 24-48 h	7
Varicella-zoster virus† Varicella	Immunocompromised	IV	10	Every 8 h	7
	Otherwise normal	Oral		Under investigation	
Herpes zoster	Immunocompromised	IV	7.5	Every 8 h	5-7
	Otherwise normal	Oral	20‡	Every 6 h	5
Epstein-Barr virus†	Immunocompromised with lymphoproliferative syndrome	IV	10	Every 8 h	10-14
Cytomegalovirus prophylaxis†	Immunocompromised	IV	10	Every 8 h	36
		Oral	20‡	Every 6 h	90

*IV indicates intravenous; CrCl, creatine clearance.

†These recommendations are the authors', not a Food and Drug Administration-approved indication.

‡Maximum dose, 800 mg.

Herpes Encephalitis.—Herpes should be suspected in any child with focal encephalitis. Fortunately, herpes simplex encephalitis is rare in pediatrics, but it is impossible to distinguish herpetic from nonherpetic encephalitis in an individual patient.²⁵ In the past, therefore, a brain biopsy was advocated prior to institution of therapy. Acyclovir has been demonstrated to be superior to vidarabine for the treatment of herpes simplex encephalitis in adults.²⁶ Because the toxicity and tolerance profile of acyclovir for this disease is quite favorable, the need for a brain biopsy before treatment is now questionable. Treatment that is instituted without a biopsy, however, is empiric because the diagnosis of herpes simplex encephalitis cannot be confirmed without a brain biopsy. Patients whose condition deteriorates despite acyclovir therapy will require aggressive neurodiagnostic evaluation including a brain biopsy.²⁷

Mucocutaneous Herpes in Immunocompromised Children.—Acyclovir is clearly indicated for this disease, but there are two choices in patient management. Acyclovir may be given prophylactically during a known period of immunosuppression, such as immediately

before and after bone marrow transplantation.²⁸ A second approach is to monitor patients closely following transplantation or induction chemotherapy and to treat those who develop symptomatic herpetic infections. Unfortunately, subtherapeutic use of acyclovir (usually intermittent oral dosing) has been associated with emergence of resistant herpes simplex virus strains.^{29,30} As we care for more and more pediatric patients with acquired immunodeficiency syndrome (AIDS), viral resistance to acyclovir could become widespread.

Herpes Simplex Viruses Resistant to Acyclovir.—Acyclovir-resistant herpes group viruses are rarely found in otherwise-normal hosts, but have been reported in immunosuppressed patients, such as bone marrow transplant recipients or persons with AIDS.^{29,30} At least three mechanisms are responsible for the development of resistance to acyclovir by herpes simplex virus strains. The first is loss of the ability to induce TK. Herpes simplex viruses that do not induce TK, called TK-negative strains, may account for about 0.1% of herpes simplex viruses found in patients' lesions. These strains are the

most common form of resistant herpes simplex viruses encountered in clinical practice. The other two kinds of resistant herpes simplex virus strains are rarely grown from cultures taken from patients. Resistant herpes simplex strains have been described that induce TK in infected cells, but the enzyme has altered specificity such that it does not phosphorylate acyclovir. Herpes simplex mutants resistant to acyclovir due to an alteration in DNA polymerase have also been described. These viruses are of concern because they have the potential to be resistant to antiviral compounds unrelated to acyclovir, such as trisodium phosphonoformate. Laboratory strains of herpes simplex with a combination of DNA polymerase and TK alterations have also been characterized. In addition to resistant herpes simplex viruses, strains of varicella-zoster virus³¹ and cytomegalovirus³² have developed resistance to acyclovir or ganciclovir in certain circumstances.

Varicella-Zoster Virus Infections

Varicella vaccine³³ will probably be licensed in the United States soon, but it

is highly unlikely that enough children will be vaccinated to achieve herd immunity for years to come. Reactivation of varicella-zoster virus as shingles will continue to keep this virus circulating in the community for a long time after the majority of children have been immunized, and vaccine failures, especially in immunocompromised children, are to be expected.³⁴ Therefore, therapy for varicella-zoster virus infections is definitely needed.

Varicella-Zoster Virus Infections in the Immunocompromised Host.—Because the risk of visceral dissemination and death from varicella-zoster virus infections in immunosuppressed hosts is high compared with that in normal children, early treatment trials focused on immunocompromised patients. Both vidarabine and acyclovir have been shown to decrease the rate and severity of complications from varicella-zoster infections.^{11,35} We recommend acyclovir because it has proved to be superior to vidarabine in two comparative trials.^{36,37} Varicella-zoster virus codes for TK, and acyclovir triphosphate inhibits varicella-zoster virus DNA polymerase in infected cells. However, varicella-zoster virus is 4 to 10 times less sensitive to acyclovir than herpes simplex virus, and, therefore, a higher dose is needed to treat varicella-zoster infections (Table 2). Like herpes simplex virus, resistant TK-negative varicella-zoster virus strains may be selected for by suboptimal therapy.³¹

Varicella in Otherwise-Normal Children.—Approximately 3.5 million persons develop varicella in the United States each year, resulting in the hospitalization of at least 4000 previously healthy children.³⁸ An effective therapy would be appropriate as an alternative to immunization or for treatment of vaccine failures. The use of an oral suspension of acyclovir for the treatment of varicella in otherwise-healthy children is currently being investigated.

Herpes Zoster in Otherwise-Normal Children.—Acute pain and postherpetic neuralgia are less severe in children than adults. However, some children with localized dermatomal herpes zoster are quite uncomfortable and would benefit from acyclovir therapy if it is started early in the course of the disease. Both intravenous³⁹ and oral⁴⁰ acy-

clovir have been shown to lessen the period of acute pain and hasten cutaneous healing in adults. One study has also shown that oral acyclovir reduced the rate of postherpetic neuralgia.⁴¹

Epstein-Barr Virus Infections

Because Epstein-Barr virus does not induce TK in infected cells, very little acyclovir is phosphorylated. However, Epstein-Barr virus DNA polymerase is quite sensitive to acyclovir and the small amount of acyclovir triphosphate phosphorylated by naturally occurring host cell enzymes may be sufficient to produce an antiviral effect.

In contrast to the therapeutic benefit of acyclovir in herpes simplex and varicella-zoster virus infections, treatment trials for Epstein-Barr virus infections have met with little success.⁴² This is probably because the most common manifestation of Epstein-Barr virus infection, infectious mononucleosis in the otherwise-normal host, results from injury induced by the immune response to Epstein-Barr virus rather than by active viral replication. Thus, an antiviral drug that limits viral replication usually is introduced too late in the course of clinical illness to affect the immune-mediated symptom complex. Such may not be the case for immunocompromised patients in whom a longer period of viral replication may precede clinical deterioration. The posttransplant lymphoproliferative syndrome, an unusual result of ongoing Epstein-Barr virus replication, appears to respond either to acyclovir or reduction in immunosuppression unless it has degenerated into a monoclonal malignant tumor.⁴³ Once cellular transformation or chromosomal alteration/integration has occurred, the tumor would not be expected to regress when treated with an antiviral drug. Hairy leukoplakia in patients with AIDS, a condition attributed to Epstein-Barr virus, also has been observed to respond to acyclovir.⁴⁴

Cytomegalovirus Diseases

Cytomegalovirus is the most pernicious of all the herpes group viruses. While some progress has been made in the prevention and treatment of cytomegalovirus infections in immunocompromised patients, congenital cytomegalovirus infections have not yet been shown to respond to antiviral drugs.

Congenital Cytomegalovirus Infections.—Investigators have attempted to treat congenital cytomegalovirus infections with anticancer drugs, vidarabine, and acyclovir but found no clinical benefit.⁴⁵⁻⁴⁷ It is possible that children who have milder forms of congenital cytomegalovirus infection would benefit from antiviral intervention because sensorineural hearing loss or attention deficits develop slowly after birth. Studies with ganciclovir are planned for this group of patients under the auspices of the National Institutes of Allergy and Infectious Diseases (Bethesda, Md) Antiviral Study Group.

Cytomegalovirus Infections in the Immunocompromised Host.—Two major recent advances have been made in the management of cytomegalovirus infections in immunocompromised patients. The first is the development of ganciclovir, an acyclovir derivative with increased activity against cytomegalovirus as compared with the parent compound.⁴⁸ Unlike acyclovir, ganciclovir is readily metabolized to ganciclovir triphosphate in cells infected with cytomegalovirus. Ganciclovir triphosphate is a competitive inhibitor and faulty substrate for cytomegalovirus DNA polymerase. The average inhibitory dose of ganciclovir for cytomegalovirus strains is 2.5 $\mu\text{mol/L}$ as compared with 63 $\mu\text{mol/L}$ for acyclovir.⁴⁹

No rigorously controlled clinical trials with ganciclovir have been published, but abundant data attest to its *in vivo* antiviral effect. Ganciclovir appears to be the best drug for the treatment of established cytomegalovirus disease in immunocompromised adults. Ganciclovir is given intravenously because of poor oral bioavailability. White blood cell counts should be closely monitored because neutropenia is a common side effect. Neutropenia can be alleviated by dose reduction or temporary cessation of therapy. A retrospective review of 12 pediatric patients by Gudnason et al⁵⁰ suggests that the effect of ganciclovir in children is similar to that of adults. To qualify for experimental therapy with ganciclovir, a patient must have sight-threatening or life-threatening cytomegalovirus disease documented by retinal examination or biopsy of the involved organ.

The second major advance in the management of cytomegalovirus disease in the immunocompromised host is acyclovir prophylaxis. Cytomegalovirus does not induce TK in infected human cells, but its DNA polymerase, like that of Epstein-Barr virus, is very sensitive to acyclovir triphosphate. The small amounts of the triphosphate produced in infected cells may be sufficient to prevent initiation of viral replication. Meyers et al⁶¹ demonstrated that intravenous acyclovir prevented cytomegalovirus infection and disease in seropositive bone marrow allograft recipients who received drug treatment for 36 days beginning 5 days before transplantation. These results have been confirmed and extended by Balfour et al,⁶² who performed a randomized, placebo-controlled, double-blind protocol of high-dose oral acyclovir in 104 renal allograft recipients. Acyclovir was well tolerated, even in the immediate post-transplant period, and significantly reduced the rates of cytomegalovirus infection and disease, especially in antibody-negative recipients whose donors were seropositive.

Because acyclovir can prevent cytomegalovirus disease, children who have just undergone a transplant operation and are seropositive for cytomegalovirus or who are seronegative but receive a solid organ from an antibody-positive donor might benefit from a course of prophylactic oral acyclovir (Table 2). Those who develop cytomegalovirus disease despite acyclovir prophylaxis should be treated with ganciclovir.

Immune serum globulin preparations are presently being investigated for prevention and treatment of cytomegalovirus disease. While immunoglobulin has been shown to have a prophylactic effect,⁶³ the data on treatment efficacy are not clear. There is some evidence that cytomegalovirus pneumonitis in bone marrow transplant patients is immunologically mediated and that the immune damage could be blocked by infusing cytomegalovirus antibodies.⁶⁴⁻⁶⁶ Further confirmation of this observation is required before immunoglobulin preparations can be endorsed as part of the treatment regimen for cytomegalovirus infections in marrow transplant patients. Cytomegalovirus immune globulin should not be used alone for

management of cytomegalovirus pneumonia in transplant recipients or patients with AIDS. The compelling evidence for active replication of cytomegalovirus in the lungs of these patients is the rationale to include ganciclovir in the treatment regimen.

Trisodium phosphonoformate is an attractive future candidate for treatment of cytomegalovirus disease because it is structurally different from both acyclovir and ganciclovir. Hence, viruses resistant to those nucleoside analogues should still be sensitive to trisodium phosphonoformate. Trisodium phosphonoformate treatment of cytomegalovirus disease in patients who have undergone transplants has produced encouraging preliminary results,⁶⁷ and controlled studies are planned in allograft recipients.

Respiratory Viral Infections

The development of specific therapy for respiratory viral infections was impeded for many years by the lack of reliable and rapid diagnostic techniques. Today, viral antigen assays can be performed directly on clinical specimens, or after viruses have been in cell culture for less than a day. Thus, a specific viral diagnosis can be provided quickly, making antiviral therapy practical.

Respiratory Syncytial Virus.—Considered the most important cause of bronchiolitis and pneumonitis in young children, respiratory syncytial virus is responsible for significant mortality in infants with underlying cardiac, pulmonary, or immune defects. Ribavirin, a broad-spectrum antiviral agent first synthesized in the 1970s, has been shown to inhibit replication of respiratory syncytial virus, influenza, parainfluenza, and numerous other viruses. The mechanism of action of ribavirin is not precisely known. This drug appears to interfere with steps in the capping and elongation of messenger RNA, although some antiviral effect may be due to reduction of guanine nucleosides following feedback inhibition of cellular inosine monophosphate dehydrogenase.^{68,69}

The advent of rapid and reliable diagnostic techniques for respiratory syncytial virus and a novel method of administration— aerosolization— have

triggered renewed interest in the potential treatment of respiratory syncytial virus disease. Ribavirin administered as a small-particle aerosol was shown to be rapidly deposited throughout the respiratory tract in concentrations sufficient to inhibit respiratory syncytial virus. Placebo-controlled clinical trials in a small number of patients at several medical centers have demonstrated a degree of efficacy for aerosolized ribavirin therapy in infants with respiratory syncytial virus infections.^{60,61} In one study, a dose of ribavirin administered by aerosol approximately 20 hours per day resulted in a reduction in viral load and clinical improvement.⁶⁰ Although transient anemia and elevated levels of bilirubin have been reported after oral or intravenous administration, aerosolized ribavirin has been consistently free of adverse effects.

The recent licensure of ribavirin for the treatment of respiratory syncytial virus disease has made pediatricians more aware of the utility of antiviral therapy. However, a clear consensus of who should receive ribavirin therapy has not been reached. This is partially due to the high cost of ribavirin administration (roughly \$500 to \$700 per day) and the lack of controlled studies containing substantial numbers of subjects. The decision to treat a patient with ribavirin aerosol should be based on the severity of respiratory syncytial virus disease and the child's general health. Most infants and children with respiratory syncytial virus infection have a mild, self-limited disease that does not require hospitalization or antiviral therapy. However, premature infants or children with underlying cardiac or pulmonary disease or immunodeficiency are at high risk for respiratory syncytial virus-related complications and should be considered for early therapy, even if their disease initially appears to be mild. Seriously ill children who may require assisted ventilation, such as those whose PaO₂ is less than 65 mm Hg or whose PaCO₂ is rising, have also been proposed as candidates for ribavirin treatment.^{62(pp528-530)} Although problems have been associated with the use of ribavirin in ventilators and the drug is not licensed for use during mechanical ventilation, some investigators suggest that ribavirin can be safely and effec-

tively administered by trained personnel who carefully monitor ventilator pressure and frequently change on-line filters to anticipate and prevent drug precipitation and plugging.⁶³

Ribavirin is contraindicated in pregnant women because it is teratogenic in rodents, although not in primates. Concern exists about possible exposure of hospital personnel to ribavirin while caring for patients receiving the aerosolized drug. The actual risk of ribavirin exposure to health care workers is uncertain. One study did not detect ribavirin in nurses who worked for 3 days with infants being treated.⁶⁴ In another study, ribavirin was detected in the erythrocyte fraction in 1 of 30 blood specimens obtained from 10 health care workers who had been in close contact with patients.⁶⁵ This latter study demonstrated minimal environmental contamination from intubated patients vs those who received the drug by oxygen hood or face mask. Calculations designed to demonstrate possible teratogenic levels of ribavirin based on concentrations of drug derived from air sampling techniques in this study are open to question, however. Because the basis of ribavirin-induced teratogenicity in rats is not understood, it would be prudent for hospital personnel who are pregnant or contemplating pregnancy to avoid working directly with patients receiving aerosolized ribavirin.

Influenza.—Antiviral agents for the prophylaxis and treatment of influenza infections are among the oldest drugs in our antiviral armamentarium. Amantadine, a synthetic caged carbocyclic compound, was licensed in 1966 for the prevention and treatment of the H2N2 strain of influenza A, and in 1976 for treatment of all strains of influenza A. Amantadine is thought to exert its antiviral activity by interfering with uncoating of the virus or the primary transcription of viral RNA.⁶⁶ When given shortly after onset of illness, it has been shown to reduce the incidence and severity of illness in otherwise-healthy adults.⁶⁷ Amantadine therapy should be considered for unvaccinated high-risk patients who develop an influenzalike illness during community-wide influenza A outbreaks. Prophylaxis should be considered during influenza epidemics in children who cannot be immunized or

who are exposed less than 14 days following immunization. Children who are candidates for amantadine prophylaxis include those with pulmonary disease, such as bronchopulmonary dysplasia, asthma, or cystic fibrosis, and those with chronic cardiac, renal, hematologic, or immunologic dysfunction.^{62(pp243-251)}

Because oral amantadine is well absorbed and 90% of the dose is excreted unchanged in the urine, the dose should be reduced in patients with renal insufficiency according to the package insert. Amantadine therapy has been associated with central nervous system side effects, including insomnia, lightheadedness, and difficulty concentrating, although these symptoms disappear when the drug is discontinued. Amantadine is contraindicated in patients with seizure disorders.

Rimantadine hydrochloride, an amantadine analogue widely used in the Soviet Union, has been reported to be as effective as the parent compound against influenza A viruses *in vivo*.⁶⁸ Fewer central nervous system side effects have been reported as compared with amantadine. Gastrointestinal disturbances occurred in approximately 2% of children in two studies.^{69,70} Viruses resistant to amantadine and rimantadine have been reported, but their clinical significance is not yet known.⁷¹ Food and Drug Administration licensure of rimantadine is anticipated shortly.

Parainfluenza.—Parainfluenza viruses have been associated with nearly 25% of acute respiratory infections in day-care centers and appear to be the major culprits in croup and lower respiratory tract diseases in children under the age of 2 years. Although ribavirin has reasonable *in vitro* activity against parainfluenza, clinical data on its use for the treatment of parainfluenza disease have not been published.

Rhinovirus.—Rhinoviruses, responsible for more than half of the mild upper respiratory tract infections referred to as "common colds," consist of over 100 different serotypes. This antigenic diversity has prevented the development of successful rhinovirus vaccines. The efficacy of prophylactic short-term interferon alfa has been demonstrated, although its side effects, such as nasal irritation, militate against long-term prophylaxis.⁷²

Approaches to treatment of the "cold" have not yet been successful. Interferons have not proved useful for the treatment of rhinovirus infections. Recombinant DNA technology has provided several novel approaches to the problem of the antigenic diversity of rhinoviruses. Monoclonal antibodies to prevent rhinovirus attachment have been developed,⁷³ and the use of a compound, disoxaril, that interferes with viral uncoating following penetration of the cell membrane has been reported.⁷⁴ Basic biologic processes are now better understood thanks to these new virus-specific inhibitors, making a true prevention and treatment for the common cold more feasible.

Measles

Measles remains a serious health problem in many parts of the world. Recent outbreaks have occurred in the United States despite very high immunization rates. Vaccine failures in young adults, particularly those immunized prior to 1967, may result in severe disease. A safe and effective therapeutic agent against measles could be used to treat the increasing number of immunocompromised children not effectively protected by immunization, young infants who are unable to be immunized, and older children who have not been immunized. At this time, ribavirin is one of the few antiviral compounds that inhibits measles virus replication *in vitro*.⁷⁵ Unfortunately, adequate clinical studies have not yet been performed. Several small, placebo-controlled trials of oral ribavirin, which may have been erratically absorbed, have suggested but not proved efficacy.⁷⁶ Conclusive proof of the utility of ribavirin therapy for measles infections awaits further controlled clinical studies.

Human Papillomaviruses

Papillomaviruses are important causes of benign and malignant tumors in both immunocompetent and immunocompromised hosts. Although we are now convinced that warts come from papillomaviruses instead of toads, we know surprisingly little about the life cycle of this novel class of DNA viruses that consists of at least 60 types.

Juvenile Papillomatosis.—This potentially life-threatening disease ap-

Table 3.—Antiretroviral Drugs Currently in Clinical Trials*

Generic Name	Tradename	Class of Compound	Proposed Mechanism of Action	Formulations	Major Toxicity
AL721	AL721	Lipids	Inhibits viral attachment	Oral	Diarrhea
CD4	Not assigned	Polypeptide	Blocks CD4 receptor for HIV	IM	Not known
Dextran sulfate	Uendex	Sulfonated carbohydrate	Inhibits viral attachment	Oral	Gastrointestinal irritation
Dideoxyinosine	Not assigned	Purine nucleoside	Inhibits reverse transcriptase	Oral	Peripheral neuropathy
Dideoxycytidine	HIVCID	Pyrimidine nucleoside	Inhibits reverse transcriptase	Oral	Peripheral neuropathy
Ribavirin	Virazole	Purine nucleoside	Inhibitor of RNA processing, transcription	Oral, IV	Anemia
Trisodium phosphonoformate	Foscarnet	Pyrophosphate	Inhibits reverse transcriptase	IV	Renal
Zidovudine	Retrovir	Pyrimidine nucleoside	Inhibits reverse transcriptase	Oral	Bone marrow suppression

*The only compound presently Food and Drug Administration approved is zidovudine. HIV indicates human immunodeficiency virus; IM, intramuscular; and IV, intravenous.

pears to be vertically transmitted from a mother with genital warts. Surgery is the only viable management option at present. Specific antiviral drugs are urgently needed to combat this entity. A recent article indicated that recombinant interferon alfa was of no value in the long-term management of respiratory (juvenile) papillomatosis.⁷⁷

Warts.—The most common manifestation of human papillomavirus infections are plantar or hand warts. The preferred therapy is to destroy or remove viral-infected tissue by sonication, freezing, or surgery. Although experimental therapy with topical or intralesional interferon has been attempted for condyloma acuminatum, a sexually transmitted papillomavirus infection, lasting responses to therapy have not been demonstrated.⁷⁸

Hepatitis

Of the three major forms of hepatitis—hepatitis A, hepatitis B, and non-A non-B hepatitis—only hepatitis B has been a target for antiviral therapies. Single-agent chemotherapy using vidarabine, its soluble monophosphate derivative vidarabine monophosphate, and acyclovir have had little effect on chronic hepatitis B.⁷⁹ Combinations of interferon alfa with vidarabine monophosphate have been neurotoxic and without clinical benefit.⁸⁰ A recent promising treatment approach was the combination of corticosteroids followed

by recombinant human interferon alfa.⁸¹ Although only 18 patients were in the treatment arm of this study, 5 (22%) became hepatitis B surface antigen-negative, and 4 of the 5 lost detectable hepatitis B core antigen in their hepatocytes and developed antibody to hepatitis B surface antigen. A large multicenter trial of this treatment regimen is currently under way.

Exotic Diseases

Lassa fever, an endemic viral disease carried by rodents in western Africa, is responsible for approximately 5000 deaths annually. Investigators demonstrated a significant reduction in the case-fatality rate when oral or intravenous ribavirin therapy was initiated within 6 days after onset of fever.⁸²

In addition to the study with Lassa fever, ribavirin has been shown in vitro to inhibit the replication of Hantaan virus, a Bunyamwera virus responsible for Korean hemorrhagic fever.⁸³ The Hantaan virus study could be pertinent to the United States because California encephalitis, our most common form of arboviral encephalitis, is also caused by a Bunyamwera virus.

Human Immunodeficiency Virus (HIV) Infections

A nationwide effort under the aegis of the National Institute of Allergy and Infectious Diseases and the National Cancer Institute, Bethesda, Md, is un-

der way to develop and test candidate drugs against the HIV, the cause of AIDS. A network of 45 AIDS Clinical Trials Units has been established and includes 11 pediatric units. The entire program is called the AIDS Clinical Trials Group.

At the present time, the most promising drug for the treatment of AIDS is zidovudine, which inhibits the reverse transcription of HIV RNA to DNA (Table 3). Zidovudine has been shown to ameliorate, at least temporarily, the neurologic abnormalities associated with pediatric AIDS.⁸⁴ Zidovudine is being intensively studied under pediatric protocols conducted by the AIDS Clinical Trials Group, which include its use in combination with immunoglobulin and a placebo-controlled study in HIV-infected children with minimal symptoms. An exciting concept that is currently being evaluated by the AIDS Clinical Trials Group is the administration of zidovudine to pregnant, HIV-infected women between the 26th and 38th week of gestation or to 1-day-old neonates in an attempt to prevent perinatal acquisition of the virus. Unfortunately, virologists have not yet determined the best test to gauge the antiviral effect of zidovudine. The dilemma is that peripheral blood mononuclear cell cultures often remain culture-positive for HIV during therapy, and decreases in serum p24 antigen levels (a test used to detect amounts of HIV protein) can be documented in only

some cases because the majority of HIV-infected patients have undetectable serum levels of p24 antigen when therapy is started. Potential problems with zidovudine include bone marrow toxicity that can be dose-limiting, and the emergence of resistant HIV strains during therapy.⁸⁵ This recurring specter of viral resistance to antiviral drugs has spurred the development of rapid antiviral sensitivity assays, such as described by Swierkosz et al.⁸⁶

Children represent a minority of the HIV-infected patients in the United States. Therefore, pediatric treatment protocols have lagged behind studies designed for adults. A number of drugs are now being tested in children, including dideoxycytidine, dideoxyinosine, ribavirin, and soluble CD4 (Table 3). An important strategy being investigated in adults would definitely be applicable to children. That strategy is to treat asymptomatic patients with antiviral drugs before severe immune dysfunction develops in order to lengthen the time from infection to expression of HIV disease. We encourage physicians caring for HIV-infected children to contact the nearest AIDS Clinical Trials Unit or the National Institute of Allergy and Infectious Diseases AIDS Clinical

Trials Information Service (1-800-TRI-ALS-A) for details about available trials, including the doses used in these protocols.

THE FUTURE

Two major events have accelerated progress in antiviral chemotherapy. The first was the development of acyclovir. The 1988 Nobel Prize in medicine was shared by three investigators. Two of them, Gertrude Elion and George Hitchings, attained the Nobel Prize in part because of their research on acyclovir. The success of acyclovir has accelerated collaborative efforts in antiviral research between universities and the pharmaceutical industry. Before acyclovir, antiviral drugs were considered by most potential industrial sponsors to be too risky to warrant the expense required to develop them.

The other event, of course, is the global tragedy of AIDS. A desperate need to develop AIDS treatments is producing a proliferation of antiviral compounds. Nearly every step in the unique replicative cycle of HIV has been targeted for antiviral attack. Drugs that inhibit a specific stage of viral replication — reverse transcription — are presently the focus of attention, but

future agents are being designed to block even earlier stages of viral infection, such as attachment, penetration, and uncoating. Soluble CD4, for example, is a promising polypeptide that could prevent attachment of HIV to the cell, or halt cell-to-cell transfer of the virus.⁸⁷ Utilizing the tools of molecular virology and genetic engineering, virologists are designing an increasing array of compounds that interfere with viral regulatory genes, downregulate viral production, or cause structural genes to synthesize defective, noninfectious viral particles. The most promising drugs that pass safely through preclinical screening will be funneled into the national testing network. We believe that the experience being amassed in these national collaborative AIDS clinical trials will not only be relevant to AIDS, but will also serve as an invaluable resource for the development of antiviral treatment strategies against many of the common viral diseases of children.

This investigation was supported in part by grants AI 27661, AM 13083, and CA 21737 from the National Institutes of Health, Bethesda, Md, and by a grant from the Minnesota Medical Foundation, Minneapolis.

Injuries Among 4- to 9-Year-Old Restrained Motor Vehicle Occupants by Seat Location and Crash Impact Site

Phyllis Agran, MD, MPH; Diane Winn, RN, MPH; Debora Dunkle, PhD

• Four- to 9-year-old children are a special group with respect to motor vehicle occupant restraints. Having outgrown child safety seats, they are often placed in adult seat belts. This study was undertaken to examine patterns of injury among restrained 4- to 9-year-olds by seat location and crash impact site. The data were obtained from an ongoing hospital-based monitoring system. Seventy percent of the sample sustained a head or face injury. Upper-torso and extremity injuries were infrequent. Lower torso injuries occurred primarily in frontal impacts in both the back and front seats. Frontal impacts resulted in a greater proportion of serious injuries than rear impacts. The most serious injuries, however, occurred to children seated on the side of impact in lateral collisions. Questions must be raised regarding the appropriateness of the present restraint system for young children. Recommendations, given current seat belt systems, are provided. However, technological improvements in vehicle design and belt systems are needed to improve protection, particularly in lateral impacts.

(AJDC. 1989;143:1317-1321)

A marked increase in restraint use among motor vehicle occupants of all ages, including children, has occurred as a result of mandatory restraint use laws and education regarding the protective effects of seat belts and child safety seats. The effectiveness

For editorial comment see p 1271.

of restraint legislation as well as the effectiveness of seat belts and child safety seats in reducing fatalities and injuries has been documented.¹⁻⁴ As restraint use increases, many restrained occupants escape injury in vehicle crashes. However, the increase in restraint use may also result in an increase

in the number of restrained occupants involved in crashes who come to the emergency department for evaluation and treatment of injuries.

Vehicle restraints that protect from injury also change the pattern and severity of injuries. Rutherford et al⁵ and others,⁶⁻⁸ for example, have reported an increase in neck injuries with increased seat belt use. Intra-abdominal injuries as well as lumbar spine injuries have also been reported in vehicle crashes as a result of hyperflexion and compression of the abdomen between the lap belt and the lumbar spine.^{10,11}

Previous research has indicated different mechanisms and patterns of injury among restrained children by age.⁹ In the pediatric population, 4- to 9-year-old children are a special group with respect to motor vehicle occupant restraint. These children have outgrown the child safety seats specially designed for younger children. They are placed in seat belt systems designed for the adult body configuration. Specific anatomic and anthropometric features are relevant to seat belt use for children in this age group. The overall weight and length characteristics of children are markedly different from those of adults. The child's sitting height is less than that of the average adult, and the center of gravity, which varies with age, length, and weight, is located on the torso above the level of the lap belt. These features alter the fit of the restraint system. The greater proportion of body mass above the belt may cause more forward motion, with an increased risk of head impact with interior parts of the vehicle. Jackknifing over the lap belt can occur in a lap belt restraint system. With lap/shoulder belts, the shoulder portion may lie over the face and neck of the young child. Another anatomic concern relates to the anchor point for the lap portion of the belt system. The lap belt is designed to restrain the body just below its center of gravity at a horizontal plane through the antero-

superior iliac crest of a standing adult. The anterior iliac crests of a child are smaller than those of an adult and are not fully developed to serve as anchor points for a seat belt until the child is approximately 10 years of age. Therefore, the belt may ride up over the abdomen of the young child. Related to this is the fact that the intra-abdominal organs of young children are less protected by the bony pelvis and thoracic cage compared with adults.¹² The tilt of the child's pelvis and the maintenance of upright posture also influence the fit of the seat belt. In addition to these physical features, the behavioral characteristics of young children may influence the protective effects of seat belts, eg, the child may readjust his or her seating position, lean forward and move about, or engage in activities that alter the proper "fit" of the belt system.

This study was designed to examine patterns and severity of injury among restrained 4- to 9-year-old children by seat location and crash impact site. The intent of this study was to analyze injuries of restrained children, not to compare restrained and unrestrained children.

METHODS

Data were obtained from a larger, ongoing hospital-based monitoring system for pediatric motor vehicle occupant trauma. The system has been in operation since 1981 and consists of nine hospital emergency departments and the coroner's office in a single urban county with a population of approximately 2 million. Hospitals for this system were selected on the basis of geographic location and annual number of emergency department visits. Four of the five designated trauma centers were included.

Data were collected on all children through the age of 14 years who came to the emergency department for evaluation and treatment of injuries after involvement in a motor vehicle crash. The parent or guardian completed a questionnaire at the time of the emergency department visit or through a follow-up telephone interview. Questions included age of

the child, seat location, restraint use, how the child was injured, type of crash, and crash impact site(s). Data on injuries, treatment, final diagnosis, and disposition from the emergency department were provided by emergency department medical staff or were abstracted from the medical records.

Information on restraint use was initially obtained through parent report. In the course of the interview the parent was asked the following question: "At the time of the accident was your child: sitting alone, standing alone, in the arms or lap of another passenger, lying down, wearing a seat belt (lap or lap/shoulder belt), in a child safety seat, or other?" This question was embedded within a series of questions regarding the child and the crash to decrease the chance of biasing responses in favor of restraint use. For those who indicated that the child was restrained, additional questions were asked regarding how the child was injured and what happened to the child and the restraint system during the crash. All of these cases were reviewed by the research team using hospital records and available newspaper and police reports. Cases in which the research team doubted whether the child was restrained were coded as such and were removed from this analysis.

Three injury measures were used. Specific injuries sustained by each child were coded. Severity of injury was coded using the Abbreviated Injury Scale (AIS-85).¹³ The AIS is scored as follows: AIS=1, minor; AIS=2, moderate; AIS=3, serious; AIS=4, severe; AIS=5, critical; and AIS=6, untreatable. Utilizing the AIS scoring method, a Maximum Abbreviated Injury Score (MAIS) that represents overall injury severity was assigned to each case. For children with multiple injuries, the MAIS is the single highest AIS code; for children with only one injury the AIS is also the MAIS. Injuries were also assigned to the following anatomic sites: head and face, upper torso, lower torso, upper extremity, lower extremity, and spine, and the highest AIS for each anatomic site was determined.

The sample consisted of children 4 through 9 years of age who were seen in monitored emergency departments or the coroner's office after involvement in a motor vehicle crash between 1981 and 1987. Only restrained children who were involved in a crash between two passenger vehicles with a single impact site were included in the analysis. Multiple vehicle crashes, rollovers, crashes involving trucks and other nonpassenger vehicles, and crashes with objects were excluded from the analysis. The analysis also excluded cases in which there was more than one crash impact site. The analysis was confined to the three most common passenger seating positions (front passenger, back passenger, and back of driver [back outboard seats]) and three types of impacts (lateral, frontal, and rear). There were 131 cases of 4- to 9-year-old restrained children seated in these seat locations who were injured in the three types of vehicle-to-vehicle crashes.

The cases were placed into one of three groups based on impact site. Group 1 cases included children in all three seat locations who were involved in lateral impact collisions. A comparison was made between on-site (impact on the side where the child was seated) and off-site (impact on the side opposite the child) lateral impacts. Group 2 cases included children in the back seat involved in frontal or rear impacts. Those in the back middle seat were eliminated because of small numbers and differences in the kinematics of occupant movement and occupant contact areas in this position compared with the outboard positions. Group 3 cases included children in the front passenger seat involved in frontal or rear impacts.

Group	Seat Position	Impact Site Comparison
1	Front passenger and back outboard	Lateral (on site vs off site)
2	Back outboard	Frontal vs rear
3	Front passenger	Frontal vs rear

Analysis consisted of comparisons of overall injury severity scores (MAIS). The anatomic site of injury within each group for the various impact sites was also compared using χ^2 analysis. The analysis of variance statistical test was used to compare overall injury severity and severity of head and face injuries for the various impact sites. Small numbers and primarily minor injuries prevented analysis of the variance in injury severity to other body areas. $P \leq .05$ was considered statistically significant.

RESULTS

Injury Severity

Table 1 shows the distribution of MAIS by seat location and impact site. Among those in group 1 (lateral impact), all the serious injuries were incurred in on-site impacts. Forty-one percent of those in on-site lateral impacts sustained injuries with an MAIS of 2 or greater, far exceeding the proportion of serious injuries in any other group. None of those involved in off-site lateral impacts sustained more than a minor injury (MAIS=1). Among those in group 2 (the back outboard seats), 10% sustained an injury with an MAIS of 2 or greater in frontal impacts compared with 7% in rear impacts. In group 3 (the front passenger seat), all of the serious injuries were in frontal impacts; 20% of these children sustained an injury with an MAIS of 2 or greater. Of those in group 3 in rear impacts, none received more than a minor injury (MAIS=1), similar to the results seen in off-site lateral impacts. Significant differences in injury severity, however, were only found in group 1. The mean MAIS for on-site lateral impacts was 1.6, compared with 1.0 for off-site impacts ($P = .005$).

Anatomic Site of Injury

Head and Face Injuries.—Seventy percent of the children sustained an injury to the head or face. Although there were no significant differences in the percentage who sustained head and face injuries within each group, trends were apparent. The largest proportions were in frontal impacts in both the back (81%) and front (77%) seats. Head and face injuries were somewhat less frequent among those in rear impacts, although a greater percentage was seen among those in the back seat (67%) compared with the front seat (50%). The only significant difference in the severity of head and face injuries was found in

group 1; on-site lateral impacts resulted in more serious head and face injuries than off-site lateral impacts ($P=.03$, Table 2).

Torso Injuries.—Upper-torso injuries were infrequent, sustained by only 6% of the sample. No significant differences were found between seat location and impact sites, and the injuries were predominantly minor (AIS = 1).

Lower-torso injuries were incurred by 18% of the sample (Table 3). In both the back and front seats (groups 2 and

3), frontal impacts resulted in a significantly greater proportion of lower-torso injuries than did rear impacts. Most of the injuries were minor abrasions or contusions. Two children with serious torso injuries were in the front seat in frontal impacts, and the other was in the back seat in an on-site lateral impact.

Extremity Injuries.—Upper-extremity injuries were incurred by 11% of the sample. Lower-extremity injuries were also sustained by 11% of the sample. There were no significant dif-

ferences in the proportion of extremity injuries by seat location and impact site for either upper or lower extremities. One lower-extremity fracture occurred in a lateral on-site impact, and two occurred in the back seat by contact of the leg with the back of the front seat in rear impact collisions.

Spine Injuries.—Spinal injuries were predominantly rear impact phenomena (Table 4). By far the greatest proportion was seen among those in the front seat (42%), followed by those in the back seat in rear impacts (22%). The injuries were predominantly minor strains. Only one child, 6 years of age, who was in the back seat in a rear impact, sustained a serious spinal injury. This child struck the back of the front seat and sustained a cervical spine subluxation and multiple skull fractures.

Case Descriptions of Seriously Injured Children

Fifteen percent of all children sustained an injury with an MAIS of 2 or greater. Over half of the serious injuries (MAIS ≥ 2) were internal head injuries. Case descriptions are presented in Table 5.

Group 1 (Outboard Position, Lateral Impact).—Among all of the seriously injured restrained children with an MAIS of 2 or greater, the greatest proportion consisted of children in the outboard seating positions involved in on-site lateral impacts. In fact, all of the serious injuries in lateral impacts were to children seated on the side of the impact of the crash. The major injury pattern in these children was either a serious head injury or an extremity injury. This occurred in both the back and front seats in lap as well as lap/shoulder belts. Vehicle intrusion in a number of these cases indicates the severe nature of several of these lateral impacts.

Group 2 (Back Seat, Frontal or Rear Impact).—In this group, serious injuries were equally divided between frontal and rear impacts. The serious injuries were either head injuries primarily caused by hyperextension of the upper torso over the lap belt and impact with the back of the front seat or extremity fractures, also caused by impact with the back of the front seat. No serious abdominal injuries were seen in this group. Only one child sustained a serious spinal injury. This involved a 6-year-old in a rear impact who struck the

Table 5.—Serious Injuries in Restrained 4- to 9-Year-Olds by Seat Location and Impact Site

Patient No./ Age, y	Seat Location	Impact Site	Restraint	Mechanism of Injury	Injuries	Maximum Abbreviated Injury Score
Group 1 (Front or Back Outboard Seat, Lateral Impact)						
1/9	Front passenger	Lateral (on site)	Restrained, presumably lap/shoulder	Intrusion of vehicle, interior impact	R fractured ribs, lung contusion, subarachnoid hemorrhage, R frontal hematoma	4
2/5	Front passenger	Lateral (on site)	Lap/shoulder	Intrusion of vehicle, interior impact	R femur fracture, lip contusion	3
3/9	Front passenger	Lateral (on site)	Lap/shoulder	Intrusion of vehicle, interior impact	Depressed R frontal skull fracture, head laceration, R leg contusion	3
4/7	Front passenger	Lateral (on site)	Lap	Hit windshield	L skull fracture (vault), concussion, L forehead laceration, knee abrasion	2
5/9	Front passenger	Lateral (on site)	Lap/shoulder	Intrusion of vehicle, interior impact	Concussion, R clavicle fracture, R leg contusion	2
6/8	Back passenger	Lateral (on site)	Lap	Unknown	L cerebral contusion, L parietal skull fracture, bladder contusion	3
7/9	Back driver	Lateral (on site)	Lap	Hit door	Concussion, L forehead hematoma	2
8/5	Back driver	Lateral (on site)	Lap	Hit door	L clavicle fracture, L head and hip contusions	2
9/4	Back driver	Lateral (on site)	Lap	Hit door	L clavicle fracture, L head contusion	2
10/7	Back driver	Lateral (on site)	Lap	Flying glass	Head laceration	2
11/7	Back driver	Lateral (on site)	Lap	Hit back of seat	L humerus fracture, L leg abrasion	2
Group 2 (Back Outboard Seat, Frontal or Rear Impact)						
12/5	Back passenger	Rear	Lap	Back seat pushed up against front seat	Bilateral femur fractures, R cheek and L elbow abrasions	3
13/6	Back passenger	Rear	Lap	Hit back of front seat	Depressed fracture of L occipital skull, bilateral comminuted fracture of frontal skull, subluxation of cervical spine	3
14/6	Back passenger	Frontal	Lap	Hit back of front seat and strained against seat belt	Concussion, facial laceration, abdominal contusion	2
Group 3 (Front Passenger Seat, Frontal or Rear Impact)						
15/8	Back driver	Frontal	Lap	Hit back of front seat	Extensive facial laceration	2
16/4	Front passenger	Frontal	Seat belt	Injured from seat belt	Ileal perforation with peritoneal hemorrhage	5
17/9	Front passenger	Frontal	Lap/shoulder	Hit windshield	Depressed occipital skull fracture, concussion, facial laceration	3
18/8	Front passenger	Frontal	Lap/shoulder	Hit dashboard and windshield	Cerebral edema, small contusion on forehead	3
19/7	Front passenger	Frontal	Lap/shoulder with shoulder portion behind	Hit dashboard and strained against seat belt	Concussion, abdominal contusions, forehead abrasions	2
20/9	Front passenger	Frontal	Lap/shoulder with shoulder portion behind and belt not securely fastened	Came out of seat belt and hit windshield and dashboard, striking abdomen and face	Liver laceration, facial abrasions	2

back of the front seat and sustained multiple skull fractures and subluxation of the cervical spine.

Group 3 (Front Seat, Frontal or Rear Impact).—All of the serious injuries to this group of children in the front

seat involved in frontal impacts. One child sustained an ileal perforation caused by the seat belt. All of the other seriously injured children struck the front of the vehicle. In two cases the shoulder part of the belt was not proper-

ly used; the shoulder portion of the belt was flipped behind the child. One child sustained a liver laceration, the other, a serious head injury. In the other two cases, even though the children were using the shoulder portion of the seat

belt, they were still moved forward and hit the windshield or dashboard, sustaining serious head injuries.

COMMENT

This study was undertaken to examine injuries sustained by children 4 to 9 years of age who were restrained at the time of a motor vehicle crash. This age group was selected because it is a special group with respect to occupant protection. These children have outgrown the child safety seat and are placed in a seat belt system designed for the adult body configuration. Patterns and severity of injury were analyzed by seat location and crash impact site. In the back seat these children were restrained in lap belts, and in the front seat they were in lap/shoulder belts.

One of the most striking features of the analysis was that among these restrained 4- to 9-year-olds there was a substantial proportion of head and face injuries; 70% of the entire sample sustained an injury to the face or head. This occurred in all seat locations and impact sites but was more of a problem in frontal impacts in both the front and back seats. Most of the head and face injuries were minor; however, 12% were serious and included injuries such as concussions, skull fractures, and internal head injuries. Several of these children struck the windshield or dashboard if they were in the front seat or the back of the front seat if they were in the back seat. A significant proportion of the most severe head injuries was sustained by children involved in on-site lateral impacts.

Another important finding was the marked proportion of serious injuries sustained by restrained children in on-site lateral impacts; 41% of these children had injuries with an MAIS of 2 or greater. The injuries primarily occurred as a result of vehicle deformation into the passenger compartment in the area where the child was seated. Thus, in the case of a serious lateral impact crash with vehicle deformation, belt systems do not appear to provide adequate protection.

A recent National Transportation Safety Board study reported a substantial number of abdominal injuries among those involved in frontal collisions who were restrained in lap belts in the rear seat.¹⁴ We did not see this in this study.

We had only two cases of serious injuries to rear-seated children in frontal impacts over the 7 years, and neither child sustained a serious internal abdominal injury. One child sustained a concussion and the other an extensive facial laceration. The serious spinal injury in this study was sustained by a child lap-belted in the back seat in a rear impact.

It is clear from this study that occupant protection in the lateral on-site impact requires changes in car design, eg, thickened doors and better padding to absorb more energy of the impact and increased space between the door and the occupant. Based on the data in this study and until improvements in vehicle design have been made, the middle rear seat may be the safest in the event of lateral impacts.

Except for on-site lateral impacts, most of the injuries to seat-belted children were minor. The seat belt-induced injuries were few and survivable. Since no children were ejected from the vehicle, it appears that seat belts prevented ejection. However, in view of the fact that a large proportion of the restrained children sustained injury to the head and face, there is a need for research to determine the fit of vehicle seat belts for children of this age. Child-sized dummies of various sizes should be developed and tested with all types of restraint systems. In addition, data on children in real-life crashes must continue to be gathered. Based on the findings of dummy crash testing and real-life crashes, seat belts may need to be modified or special seats may need to be designed to provide optimal occupant protection for children in the 4- to 9-year age group who have outgrown child safety seats.

While transitional restraint systems, ie, booster seats, are available for 4- to 9-year-old children, observational studies indicate low usage rates. At this point, crash data on young children in booster seats are not available. Additional research on the effectiveness of boosters in real-life crashes is needed. If the current booster seats are indeed protective, measures to increase usage should be addressed. Alternatively, if seat belts and current booster seats do not fit or optimally protect children who have outgrown child safety seats, it may be necessary to design a seat for the 4- to

9-year-old child similar to child safety seats.

Until a more protective system is developed and is in widespread use, children 4 to 9 years of age should use available vehicle seat belts. For children in the front seat, moving the seat as far back from the dashboard as possible, and for those in the back seat, moving the front seat forward, may eliminate some of the interior impact injuries. Use of lap/shoulder belts in the rear seat may also help to eliminate some of the more forceful head impacts. Overall, seat belts work, and parents must require children to use them.

Long-term Outcome of Adolescents With Anorexia Nervosa

Richard E. Kreipe, MD; Bruce H. Churchill; Jaine Strauss, PhD

• The long-term outcome of 49 adolescent girls hospitalized for the treatment of anorexia nervosa on a pediatric service was determined by personal interview an average of 80 ± 21 months after admission to the hospital. The mean age at follow-up was 22.7 years. Between admission to the hospital and follow-up, body weight increased, on average, from 72.1% to 96.1% of ideal. Amenorrhea occurred in all subjects, but menstruation began or resumed in 80% of patients after hospitalization, at a mean body weight $90.3\% \pm 6.5\%$ of ideal. A total of 15 pregnancies resulted in 2 elective abortions, 3 ongoing pregnancies, and 10 healthy newborns. No subject who desired to become pregnant was unable to conceive. Almost half of the subjects (22 of 45) acquired binge eating patterns after hospitalization. Overall, 86% had a satisfactory outcome. These data indicated that adolescents with anorexia nervosa can be successfully treated with a developmentally oriented, multidisciplinary approach that includes inpatient and outpatient management based in pediatrics.

(AJDC. 1989;143:1322-1327)

Anorexia nervosa is an eating disorder characterized by voluntary starvation due to a disturbed body image in which one's body is perceived as being fat (even at normal or low weight), an intense fear of obesity, and a relentless obsession to become thinner.¹ Occurring almost exclusively in adolescent girls, it results in numerous physiologic sequelae, including extreme weight loss and malnutrition, marked hypometabolism, amenorrhea, and osteoporosis.² Mortality as high as 50% has been re-

ported, but recent reports suggest a death rate between 2% and 8%.³ Although mortality has decreased, the incidence has increased during the last few decades to "near epidemic" levels.⁴ Recent studies of anorexia nervosa among middle-class adolescent girls report a prevalence rate of between 1% and 4%.⁵ Because underlying psychological and developmental factors play a significant etiologic role, multidisciplinary treatment including medical care, behavior modification, and psychotherapy is most successful.⁶ However, because psychosocial factors often dominate the clinical presentation, the pediatrician's role in treatment often is relegated to providing medical backup rather than patient management.⁷

Since the course of the illness is protracted, determination of outcome of treatment can be made only on long-term follow-up. Morgan and colleagues⁸ advise that the follow-up interval should be at least 4 years. Most studies fulfilling this criterion among child and adolescent populations are reported in the psychiatric literature, with little attention paid to biologic outcome.⁹ Outcome studies in the pediatric literature generally have been short term.¹⁰

We report the long-term outcome of 49 girls admitted consecutively to our hospital on the pediatric service for the treatment of anorexia nervosa. All but eight patients were cared for by the same pediatrician (R.E.K.). Data on mortality, morbidity, weight, eating and purging behaviors (including crossover to binge eating), and psychosocial functioning were obtained. We also determined fertility history and the weight at which menstrual periods resumed. Specifically, we sought to describe the long-range prognosis for adolescents with anorexia nervosa whose care was managed primarily by pediatricians in a multidisciplinary health care team.

PATIENTS AND METHODS

The medical records of all girls who were admitted to Strong Memorial Hospital (Rochester, NY) during the 6-year interval between January 1, 1979, and December 31, 1984, for at least 2 weeks of treatment for anorexia nervosa ($N=62$) by a pediatrician with special interest in adolescent medicine were reviewed. Seven subjects discharged from the hospital with a diagnosis of anorexia nervosa, but who fulfilled criteria for bulimia nervosa only, were eliminated from further consideration. The remaining 55 subjects, all white adolescents who met criteria for the diagnosis of anorexia nervosa, were contacted by mail and telephone to be included in this long-term outcome study. One subject had committed suicide, 2 refused to participate, two gave limited information, and 1 could not be located. The remaining 49 subjects (89% response rate) form the study sample.

Structured personal interviews were held with 47 subjects; parents alone provided information for 2 subjects. Four patients did not complete the entire interview, resulting in a denominator of 45 for some variables. To minimize potential bias regarding the assessment of outcome, each interview was conducted by a medical student (B.H.C.) who had previously reviewed each subject's medical record to obtain information about hospitalization, but who had had no previous contact with any subject.

The inpatient treatment program for these patients has been previously described.¹¹ All subjects received medical treatment focused on physical health and weight gain, proper nutrition, normal adolescent development, and some psychotherapy (individual, family, group, either alone or in combination) before, during, and after hospitalization. Specifically, 14 (29%) had received individual therapy only, and 2 (4%) had received family therapy only. Five subjects (10%) had received both individual and group therapy, while 14 (29%) had received both individual and family therapy. An additional 14 (29%) had received a combination of individual, group, and family therapy. At follow-up, 6 (12%) were still receiving medical treatment, 6 (12%) were in psychotherapy, but only 3 (6%) were still obtaining both medical and psychological

care for their anorexia nervosa. Although most patients received formal mental health care, we emphasize that the overall management of care of these patients was provided by pediatricians in pediatric settings.

Interview data were used to determine a score on the Global Assessment Scale (GAS) for each subject.¹² This instrument rates subjects with eating disorders in five clinically relevant areas (percentage of ideal body weight [IBW] for sex, height, and age; menstrual history; eating habits; social adjustment; and education/employment) and provides a single outcome score. By convention, scores are divided into four outcome categories: 0 to 3, excellent; 4 to 7, much improved; 8 to 11, symptomatic; and 12 to 23, poor. A score of less than 8 indicates a satisfactory outcome. Data were analyzed and tests of statistical significance were performed with the SAS computer program, release 5.18. Tables 1 and 2 show pertinent weight and demographic variables for this sample.

RESULTS

Mortality

One patient was known to have committed suicide, and 1 patient could not be contacted. Therefore, the highest possible mortality among the original 55 subjects was less than 4%. The patient who committed suicide had developed major depression requiring psychiatric care, had attempted suicide previously, and had developed intractable bulimia nervosa. Two other patients included in the study had attempted suicide.

Morbidity

The most commonly reported physical symptoms were related to the gastrointestinal tract. Eight subjects com-

Table 2.—Education, Employment, and Living Arrangements at Follow-up			
	No. (%) of Patients by Age, y		
	<19 (n=8)	19-21 (n=12)	≥22 (n=29)
Enrolled in school	8 (100)	8 (67)	8 (28)
Employed outside the home	6 (75)	10 (83)	23 (79)
Living with parents	8 (100)	7 (58)	5 (17)
Living with friends	0 (0)	3 (25)	8 (28)
Living alone	0 (0)	1 (8)	4 (14)
Living with spouse	0 (0)	1 (8)	12 (41)

plained of chronic constipation, even among those who had attained normal weight. Irritable bowel syndrome was reported by two subjects, and two others had had a perforated duodenal ulcer.

One subject who had vomited for more than 7 years reported frequent involuntary reflux of stomach contents. Significant dental enamel erosion occurred in two subjects who had been vomiting for an average of 10.5 years.

One of the youngest subjects was being studied for short stature and primary amenorrhea. One individual had developed hypothyroidism. The remaining 32 subjects had enjoyed relatively good health, except for some problems during pregnancy (see next section). More than half (59%) of patients reported no health problems after discharge from the hospital.

The majority of subjects (36 [73%]) were not taking any medication regularly. The most common prescription medicine, being taken by 5 subjects, was oral contraceptive pills. Four subjects (8%) were taking psychoactive medications: 2 were taking imipramine, 1 was taking lithium carbonate, and 1 was taking both lithium carbonate and phenelzine sulfate (a monoamine oxidase inhibitor). Three were taking bulk-forming laxatives because of persistent constipation. In general, the group was relatively healthy and did not complain of persistent medical problems.

Weight, Menstruation, and Fertility

Although the lowest weight reached by the group (\pm SD) averaged only $72.1\% \pm 9.2\%$ of IBW, at follow-up their weight had increased significantly ($t=12.2$; $P<.01$), having attained a mean of $96.1\% \pm 13.3\%$ of IBW. Seventeen individuals (35%) weighed less than 90% of their IBW, 6 individuals

(12%) were more than 110% of their IBW, and 26 (53%) were between 90% and 110% of their IBW.

All subjects experienced amenorrhea during their illness. Eleven subjects developed anorexia nervosa before menarche; the remaining 38 individuals had secondary amenorrhea. Amenorrhea persisted at follow-up in 10 subjects. Three subjects, aged 15, 18, and 19 years, had primary amenorrhea and had developed their eating disorder at the ages of 9, 12, and 12 years, respectively. One of the 10 amenorrheic subjects had resumed her menses after hospitalization but had not menstruated in the 6 months before follow-up. The present mean percentage of IBW of the amenorrheic group was $84.6\% \pm 7.1\%$ of IBW (range, 72% to 90%; Table 3).

In contrast to the amenorrheic group, the 38 individuals who were menstruating at follow-up weighed significantly more, averaging $98.9\% \pm 12.7\%$ of IBW ($t=3.4$; $P<.01$). Those who were menstruating regularly weighed essentially the same as those who had irregular or sporadic menses. One subject had regular menses at 94% of her IBW but had been cycled with hormonal replacement when she was at only 82% of her IBW; the other four subjects taking oral contraceptives had started taking them after their periods had resumed spontaneously.

Overall, 39 (80%) of 49 subjects had gained sufficient weight at some time after hospitalization either to initiate or to regain menstruation. Eight of 11 patients who had primary amenorrhea eventually began to menstruate. Their average age at menarche was obviously delayed, averaging 16.3 years. Although 31 (82%) of 38 subjects with secondary amenorrhea eventually resumed menstruation, the interval from

*Includes two pregnant subjects whose weight is not included in the determination of mean percentage of IBW.

†Two subjects (one who began menses because of hormonal replacement and another whose return of menses was delayed by the occurrence of hypothyroidism until the patient reached 72 kg) are not included in the determination of the mean percentage of IBW.

the cessation to the return of menses varied widely, from a few months to more than 6 years. The reported weight at which menses returned averaged $90.3\% \pm 6.5\%$ of IBW, with a range of 79% to 101% of IBW. There was not a significant difference in the percentage of IBW on return of menses for those who were menstruating sporadically compared with those who were menstruating regularly (92.8% vs 89.5% of IBW).

Thirteen subjects were married; 8 of them had become pregnant. These women had experienced 14 pregnancies and 10 deliveries since the onset of their anorexia nervosa. Three were pregnant at the time of follow-up, and another had had an induced abortion. One of the unmarried subjects also had had an induced abortion, bringing to 15 the total number of known pregnancies in the sample. No miscarriages were reported. There were 2 complicated pregnancies, both occurring in the same indi-

Table 4.—Food-Related Habits Before and After Treatment Started and at Follow-up (N = 45)

Habit	No. (%)		
	Before Treatment Started	After Treatment Started	At Follow-up
Daily food restriction	45 (100)	...	12 (27)
No food restriction	0 (0)	...	20 (44)

vidual; toxemia occurred in the first and gestational diabetes in the second pregnancy. All 10 offspring of the 7 subjects who had given birth had uncomplicated neonatal courses.

No one reported infertility. All of those who desired to become pregnant had been able to do so within 1 year. One of the three pregnant subjects had been taking birth control pills until 8 months before data collection. She became pregnant 4 months after the interview.

In summary, 80% of patients regained their menstrual periods when their weight rose to within 10% of ideal. No one desiring pregnancy was unable to conceive. When subjects did conceive, there was no evidence of adverse neonatal outcome.

Food-Related Habits

Detailed histories about eating and weight loss methods obtained from 45 subjects are summarized in Table 4. All subjects, by definition, had engaged in daily food restriction before treatment began. At the time of follow-up, 44% of subjects reported no regular dieting behavior, while 27% reported daily food restriction and 29% limited their intake, but not on a daily basis. Compulsive exercise was a commonly used means of weight control, employed by 73% of subjects before treatment started. At follow-up 38% still exercised regularly to control their weight.

Purging (vomiting or laxative use) as a means to lose weight was used at some time in the course of the illness by more than half of the subjects (23 of 45). Ap-

proximately one half of this subgroup initiated the use of these methods of weight control before treatment; the other half started them only after treatment had started. Four individuals (9%) were still using laxatives to control weight at follow-up. In contrast, 10 subjects (22%) were still vomiting at follow-up; 6 had used this method of weight control before treatment, but 4 had not begun to vomit until after treatment started. Three of the 4 who were using laxatives were also vomiting to control weight. The use of ipecac, diuretics, or appetite suppressants was rarely reported, as expected in a group of patients who primarily restrict intake.

A significant crossover to binge eating (bulimia) did occur over the course of treatment. Only 6 subjects (13%) had given a history of any binge eating before treatment began. Of those 6 subjects, three still reported binge eating at least once a week. However, almost half (22) of the total group had begun to binge eat after entering treatment; 10 of them still engaged in binge eating at least once a week. Of the 13 subjects who reported current binge eating, 8 (62%) were also vomiting at least once a week to control weight. In summary, dieting tended to normalize, with only a quarter of the group restricting their intake daily at follow-up. Likewise, compulsive exercising decreased by half. However, binge eating, vomiting, or both were dysfunctional eating behaviors that developed during recovery from restrictive anorexia nervosa in almost half of the subjects.

Education

Thirty-nine of the 41 individuals old enough to have graduated from high school had done so. One of the 2 high school dropouts planned to return to school. Of those 29 subjects old enough to have graduated from college, 20 (69%) had completed some post-high school education, 12 (41%) had completed college, and 6 (21%) had gone on to graduate school. Their fields of study included education, medicine, nursing, nutrition, and business. Despite the high level of education already attained, 44 (90%) of the 49 total subjects had plans to continue their education. In addition, 17 (71%) of 24 subjects enrolled in school also had part-time employment.

More than one third of subjects (17 of 49) reported having had problems in school as a result of their eating disorder. Problems included being preoccupied with their weight, having difficulty concentrating, and missing school because of hospitalization.

Employment

At follow-up, 39 subjects (80%) were employed at least part time. Seven of 10 unemployed subjects were full-time students. The remaining 3 individuals who were neither employed nor in school were all caring for their children at home. Among the 21 subjects who were not in school but who were employed outside of the home were 3 teachers, 2 nurses, 2 business managers, a nutritionist, and an investment broker. Overall, 5 subjects worked in food-related services full time.

In contrast to education, only 8 (16%) of 49 subjects reported having had difficulty finding or maintaining employment because of their anorexia nervosa. Five (62%) of these 8 also experienced problems with school. Overall, 4 subjects noted how their compulsivity and rigidity had diminished their efficiency and satisfaction at work. Two subjects felt limited by their diminished physical capacity; 1 subject who developed bulimia nervosa had difficulty because of binge eating at work as an ice cream vendor. Concerns about the types of jobs available to adolescents (mostly low-paying jobs related to food that present little challenge or potential for advancement) were expressed by 62% of those having trouble with work.

GAS Scores

The GAS outcome category could be determined for 48 subjects; the patient who died was included in the "poor" category. More than half (55%) of the subjects had an excellent outcome by GAS standards. Fourteen (31%) were in the "much improved" category, while 7 (14%) were in the "symptomatic" or "poor" group. The overall mean GAS score was 3.53 ± 3.3 . The average GAS score for those 16 subjects weighing less than 90% of their IBW was 6.00 ± 3.3 , significantly higher than the score of 1.96 ± 2.5 for the 25 normal-weight subjects ($t = 5.0$; $P < .01$).

In general, the six surviving patients rated as symptomatic or poor felt "trapped" by their illness and realized that weight loss could not solve their problems but could find no way to give up their eating disorder. Their dissatisfaction was not with feeling overweight, but with feeling powerless to control their weight. Four of the subjects in this group were vomiting daily at follow-up, and the individual who had committed suicide was driven to this act by her inability to stop vomiting. The remaining two subjects in the poor-outcome group were engaged in severe daily dietary restrictions.

Although only 21% of the total sample reported vomiting at follow-up, five (71%) of the group with a GAS score of 8 or higher reported vomiting. The mean GAS score of the vomiting group was three times that of the nonvomiting group (7.5 ± 2.7 vs 2.4 ± 2.6 ; $t = 5.5$; $P < .01$). The presence of binge eating at least once a week was only slightly less ominous and was generally associated with vomiting as well. The mean GAS score of the group that binged was 6.5 ± 3.3 , while those who did not binge averaged 2.1 ± 2.2 ($t = 5.0$; $P < .01$).

COMMENT

Anorexia nervosa traditionally has been considered a chronic condition with a variable, but generally poor, prognosis. A pediatric reference text recently summarized, "after 5 years, approximately one-third of the patients are symptom-free, one-third of the patients have symptoms but are functioning well, and one-third of the patients are still incapacitated."¹⁸ The data supporting this bleak outlook generally

come from reports of psychiatric-based treatment, in which consultation is often delayed by several years after the initiation of symptoms.¹²

Nussbaum and colleagues¹⁰ reported the first short-term outcome study of anorexia nervosa treated on a general adolescent medical service. Overall, 71% of the sample of 63 adolescents had a satisfactory outcome (GAS score, < 8), with a group mean GAS score of 5.8. That was significantly less than the 8.4 GAS score reported by Garfinkel and colleagues¹¹ in their psychiatric follow-up study. Notably, Garfinkel and associates' subjects were more severely ill than either those of Nussbaum et al or the present study group: 55% of subjects had had one or more previous admissions for the treatment of anorexia nervosa, more than 3 years had elapsed from symptom onset to consultation, and the mean body weight of the group on entry into care was only 64.9% of normal. In contrast, only 51% of Nussbaum and associates' subjects were hospitalized, and they averaged slightly more than 1 year from symptom onset to treatment. The present study group had been dieting, on average, only 1.6 ± 1.2 years before the first hospitalization.

Nonetheless, the mean GAS score of 3.5 ± 3.3 in our sample was significantly lower than those in both of these reports ($P < .01$), with a satisfactory outcome in 86% of our subjects. Although all of our subjects were hospitalized, at follow-up only 29% were binge eating and 27% were restricting food intake daily. These apparently better results may be due to different sample characteristics, different treatment methods, or a longer follow-up interval. We found, as have others, that vomiting (reported by 21%) and, to a lesser extent, binge eating (reported by 29%) were associated with an unsatisfactory outcome.

The mortality of less than 4% is similar to that in other reports in the literature.⁸ Close medical surveillance should eliminate death due to malnutrition. Death by suicide, on the other hand, is more difficult to control and has become the most common cause of death among persons with eating disorders. The only known death in our sample was due to suicide.

Our treatment emphasizes develop-

mentally oriented, multidisciplinary care based in pediatrics. After discharge from the hospital, subjects were followed up as outpatients for varying lengths of time, receiving various types of medical, psychological, and pharmacologic treatment as dictated by their specific needs and course of illness. Almost all subjects received individual psychotherapy, and almost half participated in family therapy. Treatment was provided by a variety of professionals, including psychiatrists, psychologists, and, social workers, for varying lengths of time. Because of the number of different forms of treatment and the small sample size, it is impossible to determine outcome in relation to treatment modality or duration. Although treatment does tend to be prolonged, it does not continue indefinitely. It is encouraging to find that the most commonly used prescription medicine by our patients with anorexia nervosa was oral contraceptives, one of the most commonly prescribed medications for all women in this age group. The general lack of medications and of symptoms speaks to the overall well-being of the group at follow-up. Almost three fifths of the sample reported no significant health problems after discharge from the hospital. When symptoms or morbidity did occur after hospitalization, they were most commonly referable to the gastrointestinal tract. Chronic constipation, irritable bowel syndrome, or peptic ulcer disease was reported by a quarter of the subjects. In both subjects with peptic ulcer disease, the duodenal lesion was diagnosed when the ulcer perforated, requiring emergency surgery. There were no recognized factors predisposing to perforation in either of these subjects. Involuntary esophageal reflux and dental enamel erosion occurred in subjects with chronic vomiting, as expected.¹⁴

The primary physiologic dysfunction related to anorexia nervosa that concerns most parents and many patients is amenorrhea and the possibility of infertility. Our data are encouraging in both respects. Of the subjects who developed anorexia nervosa before menarche, 73% eventually began to menstruate. More than 81% of those with secondary amenorrhea resumed menstruating.

The common factor for initiation or

resumption of menstruation appeared to be attaining a weight that was approximately 90% of IBW for height. The average weight in the amenorrheic group was significantly less than that in the menstruating group. Gaining weight appears to be a necessary, but not always sufficient, factor in resuming menstrual periods, however. One subject was amenorrheic for more than 6 years. During the last 2 years of that interval her weight did not change appreciably, but she was enrolled in medical school and under a great deal of stress. She attributed the eventual return of her periods to being more relaxed and having stable interpersonal relationships.

This study cannot fully address the issue of infertility in anorexia nervosa, since not all of the subjects were sexually active or desiring to become pregnant. Of the 15 known pregnancies in nine subjects, 2 ended in elective abortion, 3 were ongoing at the time of follow-up, and 10 went to term delivery. The seven subjects who carried their 10 pregnancies to term all had newborns with no perinatal or neonatal complications. Both of the complicated pregnancies occurred in the same subject, with no other subject reporting difficulty with pregnancy or delivery.

No subject who desired to become pregnant had been unable to do so. One nulliparous subject who wanted to have a child was not considered infertile at the time of data collection since she had stopped taking birth control pills only 8 months previously; she became pregnant 4 months later.

Just as menstruation tended to normalize, so did eating habits. At follow-up only a quarter of the sample practiced daily dietary restriction. This probably reflects the dieting habits of older adolescent and young adult women in the general population. Interestingly, only one of the six overweight individuals was dieting at follow-up. Many of the subjects reported still being concerned about their weight, even though this issue did not control their lives as it had when the eating disorder was active. Again, this may reflect a cultural bias toward thinness experienced by many girls. Several individuals remarked that they did not believe that it was possible to be "cured" of their

eating disorder, likening it to alcoholism. They continued to harbor negative thoughts about weight and used weight loss to cope with stress, even though there was no evidence of active disease. The majority did believe, however, that they had or could overcome their disorder and lead normal lives. A small number of subjects continued to have serious problems with eating and weight control. Two subjects were on severely restrictive diets. The other surviving four subjects in the "poor" outcome category all had pernicious bingeing and vomiting. All of the subjects with poor outcome appeared to have entered a "chronic" phase of their eating disorder, with little perceived hope of recovery.

A bothersome finding was the high rate of crossover to binge eating, vomiting, or both (generally not seen in restrictive anorexia nervosa) after treatment began. Binge eating was initiated in approximately one half, and vomiting in one quarter, of the subjects. Although the majority had since stopped, there were still 10 subjects binge eating and 4 vomiting to control their weight. Of the 6 subjects who weighed more than 110% of their IBW, 5 developed binge eating after hospitalization, and 3 continued with it.

What makes these practices especially vexing is the implication by some patients that their habits developed as a complication of treatment. They perceived that they were expected to "eat their way out of the hospital" and would sometimes gorge themselves to "make weight." Of course, binge eating and vomiting may be a part of the natural course of anorexia nervosa for some patients. The literature suggests that 20% to 50% of subjects diagnosed as having anorexia nervosa eventually develop bulimic symptoms.^{15,16} The clear message for clinicians, however, is that gaining weight should not be the sole focus of treatment and that unhealthy eating patterns (whether eating too little or eating too much) should be avoided, if possible.

The eating disorder did not appear to have a significant impact on ultimate educational or employment goals. The high level of education either attained or planned is in concert with the striving for achievement that is so characteristic of persons who develop anorexia ner-

vosa. In many cases their perfectionism prevents them from being able to live up to their expectations, however. A theme expressed by more than one third of the group was difficulty concentrating or paying attention in school, attributed either to low weight or preoccupation with weight. Few subjects had any difficulty finding or maintaining a job. Concern was expressed about the types of jobs available to young people with few work-related skills, with a perception that most jobs were in food-related services.

There are limitations to this present study. The data are primarily retrospective self-reported variables, with the obvious potential for overreporting or underreporting. In several cases, parents were also interviewed. We found no evidence of discrepancies between parental and patient reports. Historical data that could be corroborated in the chart were also reported accurately. Although weights were not actually measured, there was no evidence of systematic bias in the reporting of this value. Eleven patients had recent weights recorded in their medical record, with excellent agreement with

their self-report.

Several positive features of the study subjects should be emphasized. First, they constitute a homogeneous sample of adolescents with anorexia nervosa. Those who met criteria for bulimia nervosa only (who might have been included in outcome studies of anorexia nervosa before 1987) were excluded. Second, their interviews were conducted by a medical student who did not participate in the care of the patients. This lessens, but does not eliminate, potential reporting bias. Third, the sample included all patients with anorexia nervosa admitted to our pediatric service during a 6-year period. These patients were generally admitted because of extremely low weight or because of failure of outpatient treatment. Thus, our encouraging results may represent a conservative estimate of outcome. Fourth, all but eight of the patients were cared for primarily by one pediatrician; although this may limit data generalizability, it does ensure relative consistency in the treatment approach that patients received.

Our data suggest that adolescents with anorexia nervosa can be treated

successfully with a developmentally oriented, multidisciplinary approach that includes inpatient and outpatient management based in pediatrics. The overwhelming majority of patients can expect to return to normal weight and menstrual functioning, with no evidence of infertility in those whose menstrual periods return. In general, long-term achievement in education and employment do not appear to be adversely affected. Fewer than 15% of patients had severe, ongoing problems with their eating disorder. Health care providers caring for adolescents with anorexia nervosa need to be aware of the tendency to cross over to binge eating, vomiting, or both, with a negative effect on outcome. Further studies regarding the long-term efficacy of various treatment modalities and the long-term implications of various behavior patterns are required.

This study was supported in part by National Institutes of Health (Bethesda, Md) short-term training grant T35HL07496.

We wish to acknowledge the assistance of Gilbert B. Forbes, Robert A. Hoekelman, Christopher H. Hodgman, Olle Jane Z. Sahler, and Elizabeth R. McAnarney in the care of patients and the preparation of the manuscript.

Aminoglycoside Ototoxicity in Cystic Fibrosis

Evaluation by High-Frequency Audiometry

Teresa I. McRorie, PharmD; John Bosso, PharmD; Loren Randolph, MS

• In this study, we sought to determine the clinical usefulness of high-frequency audiometry (8000 to 20 000 Hz) in detecting aminoglycoside-induced increases in pure-tone hearing thresholds before they are noticed in conventionally tested frequencies. We measured hearing thresholds from 250 to 20 000 Hz in 22 patients with cystic fibrosis who were treated with aminoglycosides. The audiograms were age-matched and were compared with those from 13 patients with cystic fibrosis and 38 subjects without cystic fibrosis, all of whom had never received aminoglycoside therapy. In patients with cystic fibrosis who were treated with aminoglycosides (younger than 20 years), there were statistically significant elevations only in frequencies higher than 16 000 Hz. Patients with cystic fibrosis who were treated with aminoglycosides who were 20 years and older had elevated thresholds in all frequencies tested. Patients with cystic fibrosis who were not treated with aminoglycosides did not differ statistically from controls. High-frequency audiometry may serve as a useful measure of elevation in pure-tone hearing thresholds that precede noticeable loss of auditory acuity in patients with cystic fibrosis who are receiving long-term aminoglycoside therapy.

(AJDC. 1989;143:1328-1332)

The ototoxic and nephrotoxic potential of aminoglycoside antibiotics was revealed in the first case reports of aminoglycoside efficacy.¹ With time,

vestibular and auditory toxicity became widely known potential side effects associated with administration of compounds in this class. Using only conventional audiometry (frequency ranges, 250 to 8000 Hz), Moore et al² reported a 22.3% incidence of ototoxicity in a study of 135 patients receiving aminoglycoside therapy. Unfortunately, by the time conventional audiometry detects hearing loss, the damage is often clinically significant. Unlike aminoglycoside-induced nephrotoxicity, there is no routine indicator of subclinical ototoxic damage.

Cochlear damage caused by aminoglycosides begins at the base of the cochlea and continues toward the apex with continued exposure.³ High-frequency hearing loss is the initial manifestation of this insult, with subsequent loss in the lower frequencies. Hearing loss, as detected by pure-tone audiometry, is traditionally defined as an elevation of hearing thresholds in the conventional frequency ranges (250 to 8000 Hz) of 15 dB or more in at least two frequencies tested. This definition and the clinical significance of such loss is less clear in the frequencies above 8000 Hz.⁴ However, the knowledge that threshold elevations in the high frequencies precede conventional-frequency hearing loss with aminoglycoside exposure make it desirable to evaluate the clinical utility of high-frequency audiometry.

New calibration and instrumentation techniques have aided in the development of high-frequency audiometers with which reproducible hearing thresholds can be obtained in the clinical setting.⁴ Dreschler et al,⁵ using the calibration technique developed by Fausti et al,⁴ tested 100 ears of patients before and after the patients received a platinum derivative known to produce high-

frequency hearing deficits.⁶ A 58% incidence of hearing loss in the frequency range above 8000 Hz was demonstrated, compared with a 44% incidence if only those frequencies at 8000 Hz or lower had been assessed. These observations support the use of high-frequency audiometry in the early detection of hearing loss from ototoxic agents that initially insult the basal portion of the cochlea. It would be desirable to detect the damage when it is only in the high frequencies before the damage extends into the conventional ranges where the perception of speech is affected.

In previously published studies,^{6,7} hearing loss secondary to ototoxic stimuli was assessed by comparing one-time patient audiograms with those of individuals not exposed to ototoxic stimuli. Our study utilized an analogous study design to evaluate the effects of aminoglycosides in patients with cystic fibrosis on hearing thresholds in both conventionally tested and high-frequency ranges.

PATIENTS AND METHODS

Patients older than 6 years seen at the cystic fibrosis clinic at the University of Utah Medical Center, Salt Lake City, from August 1986 through March 1987 were considered for participation in the study. Responses in children younger than 6 years were considered unreliable due to potential inability to cooperate with testing procedures. In previous studies, it has been found that age but not sex is associated with differences in hearing in young adults.^{8,9} Therefore, healthy, age-matched volunteers were used as controls. Two controls per patient were used to increase the statistical power of the analysis of the differences between the two groups. The majority of the control subjects worked at the hospital or were children of employees and were not considered experienced listeners. Subjects signed a consent form that along with our protocol was approved by the local institutional review board. All subjects

Accepted for publication May 1, 1989.

were interviewed by the audiologist administering the test for factors known to contribute to hearing loss. These exclusion criteria included history of head trauma, severe noise exposure, ear surgery, chronic ear infections, meningitis, premature birth, hyperbilirubinemia, or family history of hearing loss. Patients and controls whose medical histories were unknown or in question were also excluded from the investigation. A period of at least 2 weeks between the last course of aminoglycoside therapy and the audiometric examination was required to reduce the detection of a temporary threshold shift.¹⁰

Thirty-eight patients with cystic fibrosis were evaluated audiometrically. Three patients were excluded after evaluation. One was excluded due to known concurrent severe noise exposure, one due to asymmetric loss in high frequencies in the left ear from unknown causes, and one due to persistently abnormal tympanometry readings after tympanic perforation. Twenty-two patients had received aminoglycosides. All of these had received at least one course of tobramycin sulfate therapy. The other aminoglycosides received were amikacin sulfate, netilmicin sulfate, and gentamicin sulfate. Thirty-eight control subjects were studied. The patients and controls were divided into six groups for analysis of the effects of a positive history of aminoglycoside exposure on hearing threshold. Patients with cystic fibrosis were divided into four groups based on the presence or absence of aminoglycoside exposure and an age of 20 years or younger. The choice of division of ages was based on the Osterhammel and Osterhammel⁹ study on age and sex variations in high-frequency hearing. The control subjects were divided into two groups based on age. The mean age, number of patients, and number of subjects per group are presented in Table 1. It should be noted that there were only three subjects in the cystic fibrosis group that had not received aminoglycosides and were older than 20 years.

The test site was the University of Utah Otolaryngology Clinic, Salt Lake City, using the IAC model 403 sound-treated booth. Ambient noise levels were measured with a model 800B sound-level meter (Larsen-Davis, Provo, Utah) and were well within the levels specified by the American National Standards Institute SC.1-1977 standards.¹¹ These standards are not applicable to frequencies higher than 8000 Hz, but there was no measurable ambient noise in the frequencies above 8000 Hz. The test equipment included a model 702 impedance bridge (Amplaid, AND-OR Distributors, Golden, Colo), a model 1704 clinical audiometer (Grason-Stadler, AND-OR Distributors), and a model 20-K high-frequency audiometer (Demlar, Chapel Hill, NC). The Grason-Stadler audi-

*Values are given as mean (SD).

ometer was equipped with TDH-39 earphones in MX-41/AR cushions and was calibrated to American National Standards Institute S.3-1969 standards.¹² The Demlar audiometer was equipped with model HV/1A earphones (Koss). The calibration of these earphones ensured that the output at each frequency, in terms of decibel sound pressure level, was the same as dial value. Frequency was measured and found to be within 3% of dial value. All calibration was accomplished using the Larsen-Davis model 800 sound level meter and associated 1.27-cm microphone and the coupler described by Fausti et al.⁴ Calibration was checked approximately every 2 months throughout the course of this study to ensure accuracy of the stimuli.

To avoid any contamination of the data from an underlying outer- or middle-ear dysfunction, an otoscopic examination was performed followed by tympanometry and acoustic reflex testing. Patients with abnormal tympanograms or absent acoustic reflexes were rescheduled for testing at a later date. Pure-tone air-conduction thresholds were determined in both ears at 250, 500, 1000, 2000, 3000, 4000, 6000, and 8000 Hz with the Grason-Stadler audiometer. These were measured using hearing threshold level units and converted to sound pressure level

units for use in the graphic comparison of high and conventional frequencies. Thresholds at frequencies of 8000 to 20 000 Hz were determined at 1000-Hz intervals using the Demlar audiometer. All thresholds were obtained using the procedure recommended by Carhart and Jerger.¹³ Each subject was given conventional audiometric instructions, and all audiometric testing was done by one of two professional audiologists holding the Certificate of Clinical Competence from the American Speech-Language-Hearing Association.

Descriptive statistics were used to represent the data. Additionally, paired *t* tests were performed to evaluate any difference between the left and right ears, to allow the data from both ears to be combined if there was no difference noted. A 99% level of confidence was used. Tests of significance were performed for each frequency where the number of subjects in each group was greater than 10. Because normal distribution cannot be assumed with a small number of subjects, the nonparametric Mann-Whitney *U* Test was used with a 95% level of confidence. Subjects whose hearing threshold exceeded the maximum output tested at any frequency were assigned a value of 99 dB for that frequency. For each frequency, the number of ears assigned this value was recorded.

A comparison of the differences between groups was performed with one-tailed Mann-Whitney *U* Tests. To preclude the possibility of detecting a difference between groups at any frequency as a chance result of performing multiple tests, the number of frequencies at which a comparison was made was limited. Subject groups were compared at 4000, 6000, and 8000 Hz measured with the Grason-Stadler audiometer. For those frequencies measured with the Demlar high-frequency audiometer, groups were compared at 16 000, 17 000, 18 000, 19 000, and 20 000 Hz.

RESULTS

Student's paired two-tailed *t* test was performed using trimmed means to detect any difference between the left and right ear. A difference was noted at the 13 000-Hz frequency in the control group ($P = .01$). Because no other differences were noted, the data are represented with results from both ears combined. The mean hearing thresholds and SDs for each frequency are presented in Table 2. These data are graphically displayed in Fig 1.

Patients Aged 6 to 9 Years

There were no statistically significant differences ($P \geq .15$) noted between patients with cystic fibrosis who had not received drug therapy ($n = 15$) and the normal subjects ($n = 18$). The data from these two groups were thus combined and compared with those from 12 patients who had received aminoglycosides. Differences between the two groups were noted at the four highest frequencies with $P \leq .009$ at frequencies of 17 000 to 19 000 Hz and $P = .00005$ at 20 000 Hz.

Patients Aged 20 Years and Older

There was an insufficient number of patients in the cystic fibrosis group who had never received aminoglycoside therapy to perform inferential statistical analysis with this group separately ($n = 3$). Therefore, in the older group, only control subjects ($n = 20$) were compared with patients with cystic fibrosis who had received aminoglycoside therapy ($n = 10$) to detect any statistically significant elevation in hearing thresholds. Differences between the two groups were noted at all frequencies tested. The level of significance was less than .001 for all of the frequencies in the con-

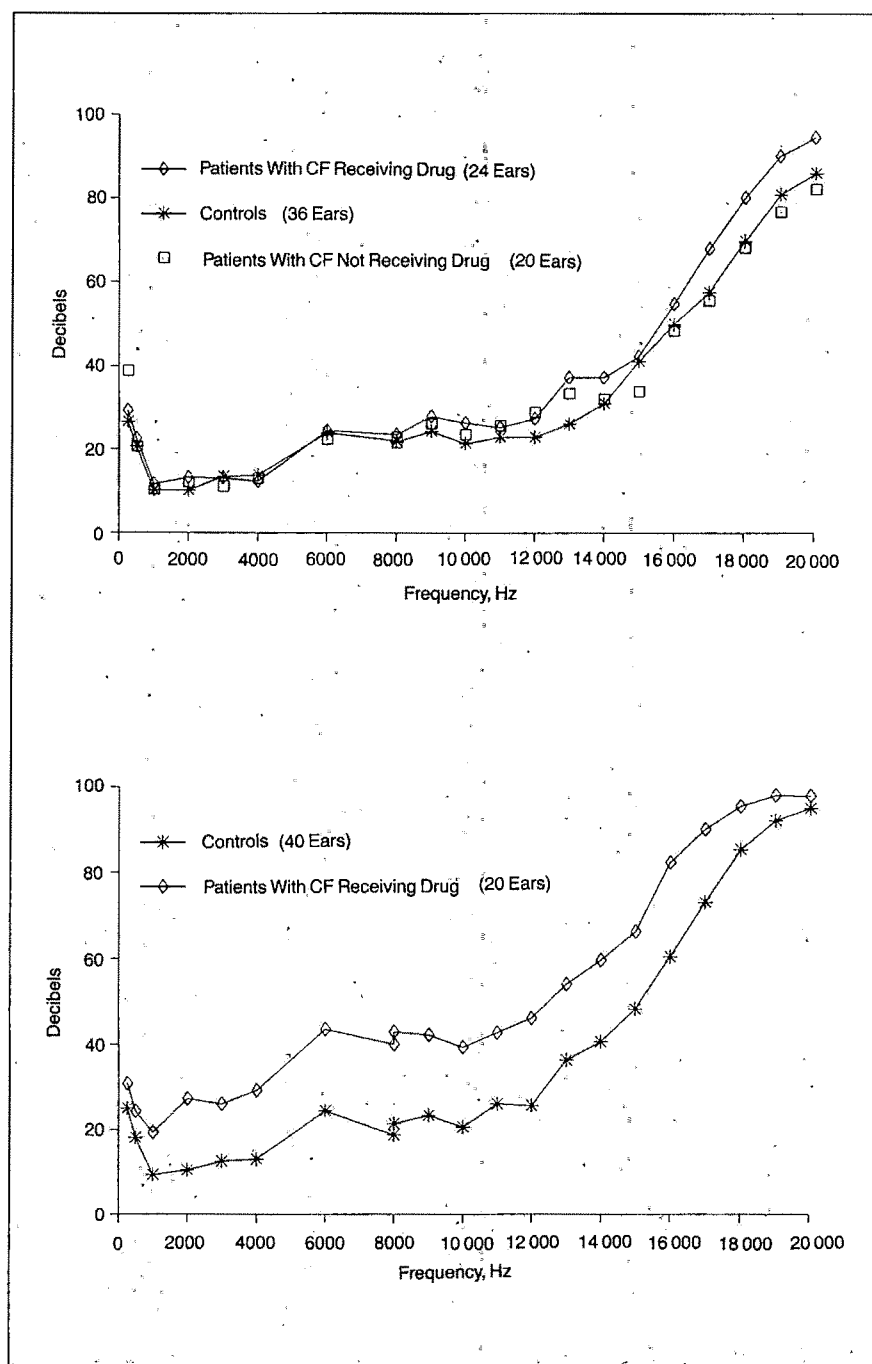

Fig 1:—Mean hearing thresholds measured at 250 to 8000 Hz with a Grason-Stadler audiometer and 8000 to 20 000 Hz with a Demlar audiometer. Conventional hearing threshold levels were converted to sound pressure level for ease of comparison. CF indicates cystic fibrosis. Top, Patients aged 6 to 9 years. Bottom, Patients aged 20 years and older.

ventional ranges and at 16 000 Hz and 17 000 Hz. The differences at frequencies of 18 000 Hz through 20 000 Hz reached significance at .005.

In Fig 2, the number of patients in both age groups who did not hear at the maximal output of the audiometer at the

individual frequencies is displayed. The number of patients who did not hear at a given frequency was greater in the groups that had received aminoglycoside therapy than in those who had not. This was true for all frequencies except 19 000 and 20 000 Hz in the older age

Fig 2.—Graphs representing the percentage of patients who did not respond to maximal stimulus of 100 dB. CF indicates cystic fibrosis. Top, Patients aged 6 to 19 years. Bottom, Patients aged 20 years and older.

group. Two patients in the older age group who had received aminoglycoside therapy had hearing deficits that extended into the frequencies below

15 000 Hz. The patients had received prolonged single courses of tobramycin therapy extending 4 months in one patient and at least 9 months in the other.

COMMENT

We found that those patients with cystic fibrosis aged 10 through 19 years who had received aminoglycoside therapy had statistically significant elevations of mean hearing thresholds in the frequencies from 16 000 Hz through 20 000 Hz when compared with controls. There were no differences in the mean hearing thresholds between the control groups and patients with cystic fibrosis who had not received aminoglycoside treatment. For those patients with cystic fibrosis older than 20 years, higher mean hearing thresholds for all frequencies tested were noted when compared with control subjects.

There are limited data for normal hearing thresholds in the frequencies above 8000 Hz. Studies establishing normal values have been performed, but a firm definition of normal hearing has not yet been determined.^{8,9,14,15} This is partly due to varying methods and instrumentation and is also largely due to the small number of ears tested to date.¹⁶ A criterion for defining high-frequency hearing loss secondary to ototoxicity is still debated due to a lack of normative data. Our data confirm values previously obtained in healthy volunteers and contributes to the normative database. In 1979, Osterhammel and Osterhammel,⁹ using a different method of determining high-frequency thresholds that incorporated a quasi-freefield technique in a soundproof booth, tested the hearing of 286 control subjects, 67 between the ages of 10 and 19 years, and 44 between the ages of 20 and 29 years. Mean high-frequency thresholds for their 10- to 19-year-old age group were in agreement with the findings in the control groups of our study. The SDs ranged from 6.6 to 19.5 dB, compared with our range of 5.9 to 21.7 dB. It should be noted that the small SDs may be an erroneous finding in the highest frequencies because a large percentage of patients did not hear at the maximal output. The means and SDs for the older age group are also consistent with the present findings, with SDs ranging from 6.8 to 16.4 dB compared with 4.9 to 21.1 dB in the present study.

Pedersen et al¹⁶ used the data from the Osterhammel and Osterhammel⁹ study to compare the long-term effects

of aminoglycosides in patients with cystic fibrosis. Forty-six patients with cystic fibrosis who had received aminoglycoside therapy were evaluated audiometrically using the same technique used by the Osterhammels in their normative study. Their criterion for determining hearing loss with one audiometric examination was not defined and it was not indicated if they used statistical methods to compare the two groups. They found that two patients had hearing loss that was attributed to tobramycin therapy. These two patients were the only patients found to have total hearing loss at some frequencies, which is markedly different from findings of our study. It is possible that this discrepancy is due to the use of a lower maximal output (decibels) in our study. More likely explanations of the differences in the findings may lie in the

potential differences in the type of overall administration of aminoglycosides to patients with cystic fibrosis in Denmark¹⁶ compared with our program.

We cannot conclude from our data that the elevations in hearing thresholds observed can be entirely attributed to aminoglycoside exposure. We did, however, control for variables that are also associated with ototoxicity. Additionally, our findings are consistent with the trends observed with the use of aminoglycosides in this population. The younger patients had, on average, received fewer aminoglycosides than the older subjects and, therefore, could be expected to have smaller hearing threshold elevations than the older patients. To accurately identify the extent to which aminoglycosides damage hearing over time, an analysis of the total amount of each of the individual amino-

glycosides received along with the time course the drug was delivered is required.

It is important to note that elevation of pure-tone hearing thresholds alone does not define hearing loss.¹⁷ However, it is known that this is the first clinically detectable sign that precedes hearing loss.¹⁰ Because of this, the differences noted in the younger age group at the highest frequencies are particularly important. High-frequency audiometry should therefore be evaluated to assess whether cessation or alteration of aminoglycoside use in patients with threshold elevations at frequencies above 8 000 Hz will prevent hearing loss in the conventional frequencies.

The authors thank Peggy Nicholes, RN, for assistance and Arnold Smith, MD, for advice.

Purpose.—This department is intended to share information concerning educational efforts in the broad field of pediatrics. We welcome studies on the following topics: undergraduate and graduate education in medicine and allied health occupations; continuing education of health professionals; education of patients and families; and health education for the general public, the community, and organizations that contribute to the promotion and improvement of the health of children.

Editorial Comment.—*You probably have a very efficient method for scheduling your patients. This has not been so easy in training program ambulatory clinics, due to variable resident levels and experience levels. The solution—computerize the system. This article shows that it can be done.*—H.D.A.

Computerized Patient Scheduling in Outpatient Residency Practices

Thomas G. Quattlebaum, MD

• A computerized appointment system is described that accommodates the special needs unique to residency training programs. Appointments are scheduled automatically according to the type of problem with which the patient presents to the office as well as the differing time requirements of faculty physicians and residents at various levels of training. The system provides for the easy and flexible scheduling of residents and the automation of appointment reminders.
(AJDC. 1989;143:1333-1336)

Patient appointments are an important part of the outpatient practice of medicine and provide benefits for both patient and physician. An effective scheduling system should allow the provision of care in the most efficient fashion for both medical staff and patients. It is widely recognized that prolonged waiting is a major cause of patient dis-

satisfaction. An ideal appointment system should keep waiting to a minimum while still providing the most efficient use of office staff and space and maximizing the number of patients that can be seen in a time period.

Several major methods are used for scheduling patients.¹⁻⁶ With the block scheduling technique, all patients are appointed for the same time. For example, all morning patients may be asked to come at 8 AM and all afternoon patients at 12:45 PM. Many traditional hospital outpatient clinics have employed this system. Although it can provide a continuous flow of patients for the medical staff, block scheduling leads to very long waiting periods for many patients.

A modified block schedule breaks a session into smaller blocks. For example, one group of patients may be scheduled at 8 AM, with other groups to arrive at hourly intervals throughout the day. Wave scheduling is a variation of the modified block system in which patients are appointed in several "waves" of more than one patient throughout an hour, usually with time at the end of

each hour for the physician to complete the care of patients appointed for that hour. Both of these methods can reduce the prolonged waiting of a block schedule, but each involves a built-in waiting time at the beginning of the hour or wave. In addition, neither method considers the time requirements of a particular patient or physician.

Individualized appointment systems give a different appointment time to each patient. Structuring the schedule so that the length of an appointment reflects a patient's presenting problem has been shown to reduce waiting times and increase patient satisfaction.^{2,6}

Outpatient scheduling in a residency program presents unique problems that are not present in a practicing physician's office. Now that many residency programs have reorganized their traditional outpatient clinics into continuity-based programs, these practices often have faculty physicians as well as interns, residents, and physician extenders seeing patients in the same outpatient location at the same time. Thus, physicians of widely varying skills are

usually practicing simultaneously in the residency program's outpatient service. The length of time allocated for patient visits ideally should reflect not only the types of problems with which the patient presents to the office but also the skills and proficiency of the physician seeing the patient. For example, an inexperienced intern often needs to discuss a relatively simple follow-up visit with an attending physician. He may require considerably more time to complete that visit than a senior resident seeing a far more complex patient with multiple medical problems.

The variable time that residents spend in the outpatient practice from month to month causes another practical difficulty in designing a patient scheduling system. For example, a resident may be in the practice only 1 half day each week while doing an intensive care rotation but 3 or more half days during the following month.

A patient scheduling system for a residency program should consider the varying needs of both patients and physicians while maintaining the timely flow of patients in the practice. It should also allow quick and flexible scheduling of residents. An ideal system would also provide for the automated printing of appointment reminders. Herein, a computerized scheduling system for microcomputers is discussed that meets these special requirements.

BACKGROUND

The pediatric residency program at the Medical University of South Carolina, Charleston, provides general pediatric training with an emphasis on primary care and continuity of care as well as traditional inpatient and intensive care experiences. A primary care practice provides the majority of the residents' experience in outpatient continuity of care. The practice consists of 3 full-time faculty attending physicians, 2 behavioral science faculty, a nurse practitioner, and 24 residents, as well as nursing and business office staff. Each resident spends part of every week in the practice seeing his or her own panel of patients. Residents spend from 1 to 4 half days each week in the practice, depending on their rotation for that month. An average of 25% of each house officer's time over 3 years is scheduled

in the practice. One or 2 attending physicians, the nurse practitioner, and 4 or 5 residents see patients during each half-day session. Behavioral science faculty see patients 5 half days during the week. Thus, a total of 8 or 9 health care providers are scheduled for each morning or afternoon session during the week.

From 1982 to 1985 a set of computer programs were developed that provided the foundation for the scheduling system. The initial programs were designed to allow the assessment and management of outpatient experiences in residency training.⁷ Billing programs were later integrated with the original programs. In 1984 and 1985 the computer system was enlarged and transferred from a mainframe computer to a microcomputer located in the practice.^{8,9}

SCHEDULING SYSTEM REQUIREMENTS

In 1986 a computerized scheduling system was developed to replace the previously used manual appointment book. A technical discussion of the design of the computer programs and the algorithms involved is beyond the scope of this article and is presented elsewhere.¹⁰ However, a general overview of the needs that determined the scheduling system's formulation is helpful in understanding the system's usefulness in a residency program.

A number of considerations led to the current system design. The simultaneous display of all physicians and their appointed patients was essential to allow a scheduling clerk to see at a glance where patients could be appointed. The system also needed to display comments for each physician and for each appointment.

A technique was needed to designate time slots that were allocated to a previous patient. For example, if a young infant were scheduled for a health maintenance visit with a first-year resident at 9:15 AM, some method was needed to show on the computer screen that the resident's time slots until 10:15 AM were assigned to that infant's well check and were thus not available for another patient appointment. Automatic computation of the differing periods needed for the various physician levels and patient types was vital for the proper functioning of the system.

A method was desired that would allow appointment reminders to be mailed selectively to patients who have an increased likelihood of missing their appointments.

Finally, easy scheduling of physicians was important. For instance, if a resident were assigned to the practice every Monday morning for a month, the system should be able to schedule all of these mornings with a single entry, rather than requiring a separate entry for each Monday. A similar ability was required for the removal of physicians from the schedule during their vacations.

TECHNIQUES USED

As shown in the Figure, the appointment entry screen used by the system displays the appointments for up to 12 physicians during a 1-hour block of time on a particular day. If more than 12 are scheduled, multiple screen displays are used to present the physicians in groups of 12 per display. Comments are displayed for each physician and are used to inform clinic personnel of each resident's current hospital or clinic rotation. This information is useful in appointing patients who make "call-in" sick visits when their assigned physician is not scheduled to be in the practice that day. These patients are usually appointed to residents on an outpatient clinic rotation.

Each July when new house officers join the residency program, their names are entered into the computer system with the date they joined the program and their residency level at that time. This information remains on file and is used by the computer to determine what a resident's level will be at the time of a future appointment. This level is used to determine the additional time needed for the type of appointment being scheduled. As seen in the Figure, the phrase "... same ..." is used on the screen to mark time slots that are committed to an earlier appointment.

APPOINTMENT ENTRY

When clerical staff wish to give an appointment to a patient, that patient's name or number is entered at the terminal keyboard. This information is checked for a match among patients defined to the system. If an exact match is

not found for alphabetical entries, a listing of patients with similar last names is displayed.

Comments are entered for each patient appointment and are used to designate for what type of visit the patient is scheduled. After the patient's name or number is accepted by the computer, the resident's level is computed. The comment for that appointment is then searched for key letters or phrases to determine the length of time required for that physician dealing with that problem. The time allocated for the various physician levels is summarized in the Table. The abbreviation WC is used to signal that the patient will be seen for a "well check" and should be given 60 minutes if the physician is a first-year

resident, 45 minutes for a second-year resident, and 30 minutes if the physician is a senior resident or an attending physician. "Brief visits" are allocated only one 15-minute time slot, regardless of the physician's level. The abbreviation WCF is used to designate the first of several well check appointments for a family. No additional time is given for these appointments beyond that allocated to subsequent family members. This technique allocates a first-year resident, for example, 1 hour for a well check if only one family member is seen and an additional 15 minutes if a second person is seen from the same family. Medical conferences are allocated 60 minutes for all physician levels. All residents are given a total of 80 minutes for

"return visits" and "sick visits," but faculty physicians are scheduled for 15 minutes for these appointments.

If the computer finds a conflict between the time required and previous or subsequent appointments, it does not allow the appointment to be entered. In addition, because several terminals can be used for data entry simultaneously, the system does not allow an appointment to be entered if it conflicts with one being entered at another terminal. Patients who need to be scheduled for immunizations, laboratory studies, etc, but who do not need to be seen by a physician are scheduled for the nursing staff. The comments for these appointments are helpful in alerting the nurses as to what studies or procedures are needed.

Function keys on the terminal keyboard allow appointment personnel to perform special tasks quickly. For example, if a patient requests an appointment with Dr X, one key is used to jump to the next session that Dr X is scheduled to be in the clinic. Another key is used to search the appointments on file to find when a patient has an appointment. This capability is useful when a patient calls to change an appointment but cannot remember the date. Another function key displays a month's calendar with the resident's sessions highlighted and notes the number of patients already appointed for each session. An additional key lists the information on file about a patient, including the assigned resident's name as well as the parent's name, address, and telephone number.

APPOINTMENT REMINDERS

Many published studies have shown that appointment reminders close to the time of the scheduled appointment reduced the number of missed appointments.¹¹ Efforts should be concentrated on those patients who are at highest risk of missing their appointments. It has been demonstrated that significant reductions in missed appointments are more likely to be achieved if appointment reminders are given to patients who have been scheduled more than 14 days before their appointment time.¹² Patients from lower socioeconomic groups are also at higher risk for missing appointments.¹¹

The scheduling system provides the automated printing of reminder postcards each week for mailing to patients who are scheduled for the following week. Cards are printed only for those appointments made more than 2 weeks before the scheduled date. These cards can be limited to those patients whose financial codes indicate that they fall into lower socioeconomic groups.

COMMENT

This system currently is being run on an IBM AT-compatible computer connected to seven terminals and four printers. These terminals are also used by office staff for billing and patient information systems, which are run simultaneously on the same computer. A simpler hardware setup consisting of a computer and one or two terminals and printers would be adequate for most outpatient residency practices. The use of several terminals allows patients to be given appointments by more than one individual and at several locations.

Printers are used with the scheduling system for making a daily list of patients and physicians scheduled for the next day's session in the clinic. This printout is helpful in locating charts for the scheduled patients before their arrival and for providing physicians and nursing staff a list of the day's patients. An "encounter form" is printed when each patient arrives. This form shows the patient's appointed and arrival times as well as demographic and billing information needed by the office staff. Space is present on the form for the physician to note the patient's diagnoses, the procedures involved in the visit, when the patient should return, and for what type

of visit. This information is used for making follow-up appointments as the patient leaves the office and for data entry into the billing system.

The automation of appointment reminders allows the office staff to quickly print postcards once each week. The criteria for printing these reminders allows them to be used in a cost-effective method by targeting those most likely to break their appointments. The effectiveness of these reminders in reducing the number of broken appointments is the subject of a current study.

Office staff have found the scheduling system simple and easy to use. With the previous manual scheduling system, busy personnel found it difficult to accurately and consistently schedule patients based on a resident's level of training and the patient's problem. Appointments were often scheduled too close together, leading to conflicts between the time allocated for one appointment and that needed for the next patient. When this happened, bottlenecks occurred in the flow of patients, leading to increased waiting and considerable patient and physician frustration. Other appointments were incorrectly made too far apart and resulted in increased physician idle time. The computerized system has provided improved patient flow while increasing satisfaction among office staff, patients, and physicians.

The benefits of the scheduling system that have been observed have led to plans for the installation of the complete scheduling system at another hospital. This new installation will allow patient and physician flow analyses and satisfaction studies to be performed both be-

fore and after installation to document in detail the improvements in patient care provided by the system. Information about the computer programs can be obtained on request.

This study was supported in part by grant 5-D28FE-14238 from the US Department of Health and Human Services.

● **Recognizing the similarity of type I diabetes mellitus to inborn errors of metabolism that have responded to carnitine therapy, we initiated a study of 54 children with type I diabetes mellitus. Examining a fasting blood sample for levels of carnitine, glucose, and glycosylated hemoglobin A_{1c}, and a urine sample for levels of ketones and glucose, we found 13 children were deficient of free carnitine (<20 $\mu\text{mol/L}$) and 30 had elevated acyl carnitine levels (>11 $\mu\text{mol/L}$). Statistical tests confirmed a significant difference between the diabetic population and normal population for reduced free carnitine, elevated acyl carnitine, and an elevated ratio of acyl carnitine to free carnitine. Also, a significant correlation was found between the levels of urine glucose and ketones and the level of acyl carnitine. Our data indicate that carnitine deficiency and relative insufficiency may be an overlooked component in the management of diabetes. (AJDC. 1989;143:1337-1339)**

Carnitine is a naturally occurring substance and a necessary cofactor in fatty acid metabolism. Specifically, carnitine functions as a cofactor of carnitine translocase, acyl carnitine transferase I, and acyl carnitine transferase II, which act to convert free long-chain fatty acids to acyl carnitines and transport them into the mitochondrial matrix (Figure). β -Oxidation of fatty acids precedes entry of the two carbon moieties into the Krebs cycle where production of adenosine triphosphate occurs. Carnitine also transports shortened acyl coenzyme A (CoA) compounds from peroxisomes to mitochondria. Through these activities, carnitine regulates the cytosolic and mitochondrial acyl CoA/free CoA ratio. Availability of free CoA is vital for maintaining adequate adenosine triphosphate production.^{1,2}

Carnitine is synthesized by the body, with the final step of synthesis occurring in the liver and kidney. Dietary sources, such as red meat and dairy products, supply an important portion of the body's carnitine stores. No pathways of degradation have been identified, with the main mechanism of loss being excretion via the urine.^{1,2} Preferential reabsorption of free carnitine is an active process with a well-defined threshold that effectively regulates plasma free carnitine levels in normal conditions, while the majority of esterified carnitine (acyl carnitine) is excret-

ed via the urine.³ Therefore, prolonged elevation of carnitine esters, such as occurs in organic acidopathies, may cause a depletion of carnitine stores. In addition, we postulate that the moment-to-moment availability of free CoA depends on free carnitine availability. A shift toward esterified CoA results in an increase in the ratio of esterified carnitine vs free carnitine, a so-called relative carnitine insufficiency, which leads to decreased energy production. Such a shift should be reversible if additional free carnitine is supplied.

Carnitine deficiency states have been

Diagrammatic representation of the function of carnitine at the inner mitochondrial membrane. All transfers at the membrane are reversible, and inadequate carnitine levels may decrease transfer of free fatty acids (FFA) into the mitochondrion as well as transfer of acyl compounds from the mitochondrion. ATP indicates adenosine triphosphate; AMP, adenosine monophosphate; CoA, coenzyme A; and PPI, inorganic phosphate.

described, and symptoms include lipid storage myopathy, cardiomyopathy, progressive muscle weakness, hepatic encephalopathy, nonketotic hypoglycemia, failure to thrive, and recurrent infections. Treatment by dietary supplementation of carnitine has been successful, in the majority of cases, in ameliorating or resolving the problems associated with low levels of free carnitine.⁴⁻⁷

Early reports by Bohmer et al¹⁸ in 1974 and by Cederblad et al¹⁹ in 1977 described no significant difference in tissue and plasma carnitine levels in diabetic patients as compared with control subjects. Later, de Palo et al²⁰ and Cederblad et al,²¹ who studied 52 patients between the ages of 8 and 20 years, both reported significantly reduced levels of total and plasma free carnitine. Cederblad et al²¹ also reported significantly increased levels of acyl carnitines in their patients. In addition, several studies have reported decreased levels of free carnitine and increased levels of acyl carnitine during diabetic ketosis.²²⁻²⁵

The metabolic dysfunction in diabetes bears a striking similarity to many of the inborn errors of metabolism that have responded well to carnitine supplementation. Diabetes, when it is poorly controlled, increases demand on carnitine stores due to the increased oxidation of fats and degradation of protein, with production of acyl CoA compounds requiring carnitine for clearance. We, therefore, hypothesize that diabetic children, specifically those whose disease is poorly controlled, have an increased incidence of reduced plasma free carnitine, elevated esterified carnitine, and altered acylated-to-free carnitine ratio, a relative carnitine insufficiency, when compared with a non-diabetic population. Also, we expect the four indicators of control of diabetes that we examine—glycosylated hemoglobin A_{1c} (HbA_{1c}), blood glucose, urine glucose, and ketonuria—will correlate with acyl carnitine levels.

PATIENTS AND METHODS

Fifty-four children with type I diabetes mellitus were included in the study. All patients attended a diabetes camp at Bearskin Meadows in the Sierra-Nevada Mountains in central California. Approval for the study was obtained from the Board of Trustees governing the camp, and all patients participated voluntarily with consent forms being

obtained from each patient or the patient's legal guardian.

A urine sample was collected, and a single blood sample was obtained by venipuncture in the morning prior to receiving insulin or eating. Blood was divided into aliquots and analyzed on site for glucose with a test strip utilizing the glucose oxidase-peroxidase reaction (Chemstrip, Boeringer Mannheim) or frozen on dry ice for shipment to laboratories for determination of carnitine levels using the modified radiometric method of Parvin and Pande²⁷ (Metabolic Analysis Laboratory, Madison, Wis) and HbA_{1c} (SmithKline & French Laboratory, Fresno, Calif). Urine was analyzed for glucose and ketones by dipstick.

All children were healthy when tested and displayed normal activity. Age, ethnic origin, diet, date of onset of diabetes, height, and weight were recorded. Control data were derived by analyzing samples taken from 20 randomly selected patients, of similar age and normal health, after random blood samples were drawn at Valley Children's Hospital, Fresno, Calif.

Data analysis was accomplished using the Student *t* test, χ^2 analysis, and multiple regression.

RESULTS

Of the 54 children studied for correlation between control of diabetes and plasma carnitine levels, 31 were boys and 23 were girls; their ages ranged from 7 to 18 years with a mean (\pm SD) of 11.9 ± 2.8 years. The group included 46 white children, 4 Hispanic, 2 Asian, 1 black, and 1 American Indian. The age of onset of diabetes was between 0.4 and 15 years with a mean (\pm SD) of 7.2 ± 3.4 years. Personal histories revealed normal diets with no vegetarians and no medications other than insulin being taken.

Thirteen patients had a plasma free carnitine level we define as deficient—less than $20 \mu\text{mol/L}$, or 2 SDs below the mean of $39 \pm 10 \mu\text{mol/L}$. The number of girls as compared with the number of boys with plasma free carnitine deficiency was significant at the $P < .01$ level, with 10 of the 13 carnitine-deficient patients being girls as compared with 13 of the 41 nondeficient patients being girls. The length of time affected with diabetes was not significantly different for the carnitine-deficient and nondeficient groups, nor did age seem to be a factor since the mean age of the carnitine-deficient group (12.7 ± 3.7 years) was not significantly different from the population as a whole.

When comparing levels of free and esterified carnitine and the ratios of the esterified to free levels of our patient population with values derived from 20 control subjects of similar age and sex distribution, the patient population was significantly different, with $P < .001$ for free and esterified carnitine and the ratio of esterified to free carnitine (Table 1).

When all indicators of diabetes control were examined (levels of blood glucose, urine ketones, urine glucose, and HbA_{1c}), 43 of the 54 patients had at least one value indicating poor control of diabetes, and 11 had all values within normal levels (Table 2).

Plasma esterified carnitine values beyond the limit of normal ($11 \mu\text{mol/L}$) were found in 30 of 54 patients (Table 2). When the patients with abnormal values for at least one of the control indicators were examined for correlation with elevated levels of esterified carnitine, we found that the urine glucose level demonstrated significant correlation at $P < .03$, and urine ketone levels dem-

Table 1.—Plasma Carnitine Levels*

	Free Carnitine, $\mu\text{mol/L}$	Esterified Carnitine, $\mu\text{mol/L}$	Ratio
Patients (n=54)	24.7 ± 6.0	12.5 ± 6.0	0.52 ± 0.31
Controls (n=20)	35.0 ± 7.4	9.3 ± 5.0	0.29 ± 0.21

*The patient population differed from the control population with $P < .001$ for all categories. All values are mean \pm SD. The ratio is that of esterified to free carnitine.

Table 2.—Incidence of Values Indicating Poor Control of Diabetes in Patients With Elevated and Normal Esters*

Characteristic	Elevated Esters (n=30)	Normal Esters (n=24)	All Patients (n=54)
Glycosylated hemoglobin A _{1c}	5	9	14
Hyperglycemia (glucose level >7.8 mmol/L)	12	7	19
Ketonuria	12	3	15
Glycosuria	23	10	33
All values normal	4	7	11

*Incidence of ketonuria and glycosuria demonstrated significant correlation ($P < .03$ and $P < .05$, respectively) with elevated esters.

onstrated significant correlation at $P < .05$. The levels of HbA_{1c} and blood glucose did not correlate with elevated levels of esterified carnitine. However, the mean level of blood glucose (7.7 ± 3.0 mmol/L) of the 30 patients with abnormally elevated esterified carnitine was significantly different from the mean level of blood glucose of the patients with normal ester levels (5.9 ± 1.8 mmol/L) at the $P < .05$ level.

COMMENT

In our population of 54 pediatric patients with type I diabetes mellitus, a statistically significant group, 24% (13/54), were deficient of plasma free carnitine. This agrees with numerous previously published observations.^{22,26} Of interest was the statistically significant number of carnitine-deficient girls (10 of 13) recorded. An explanation we offer is that the age of the girls (mean, 13.5 years) coincides with the onset of menses, and this complex event may, in some subtle way, influence carnitine levels. Certainly we know of no studies that have been directed specifically at this issue.

As we expected, the free carnitine and esterified carnitine levels as well as the esterified/free ratio of the diabetic population were significantly different from those of the normal population ($P < .001$). This is a reflection of recurrent episodes of ketosis with a concomitant need to clear acyl CoA derivatives in the diabetic patient.

When we attempted to examine degree of control of diabetes by correlating HbA_{1c}, ketonuria, glucosuria, or blood glucose levels with esterified carnitine levels, the results did not fit our hypothesis. The elevation of urine glucose and ketone levels correlated significantly with carnitine esters, but HbA_{1c} and blood glucose levels did not (Table 2). Since the amount of esterified carnitine in the blood changes on a moment-to-moment basis and reflects rapid intracellular changes in acyl CoA production, perhaps these findings suggest that acute swings in metabolism occurred throughout the night and were reflected in urine glucose and ketone values we found by collecting a sample the following morning. If such swings do not last for extended periods, HbA_{1c} would likely not be elevated, but repeated short time course episodes of

such swings would result in carnitine depletion. The lack of correlation with elevated blood glucose levels may simply be due to the fact that we did not obtain a continuous blood glucose monitoring prior to obtaining carnitine levels. Indeed, hyperglycemia may have occurred throughout the night and remained undetected in the morning sample.

In our opinion, the most sensitive indicator of carnitine insufficiency is the ratio of esterified carnitine to free carnitine, which increases during insufficiency states. During diabetic ketosis, relative carnitine insufficiency can occur due to the build-up of acyl CoA derivatives.^{21,26} This insufficiency will result first in decreased adenosine triphosphate production and, if sustained, will eventually result in outright deficiency of free carnitine as a result of urinary excretion of esterified carnitine.⁸ Carnitine deficiency, therefore, can result from repeated bouts of ketosis. Due to decreased fatty acid transport under conditions of carnitine deficiency, ketosis no longer occurs, with the result being conditions favoring the clinical phenomenon known as nonketotic hypoglycemia.

We see our findings as preliminary but suggesting that relative carnitine insufficiency may be an overlooked and treatable component in the management of diabetes. Further controlled studies on large populations of diabetic patients receiving carnitine supplements are warranted.

This study was supported in part by a grant from Sigma-Tau Pharmaceuticals, Gaithersburg, Md.

The Board of Directors and personnel at the Bearskin Meadows Camp, the Valley Children's Hospital Laboratory, and the University of California, San Francisco, Medical Library staff cooperated in this study, and Lawrence Linn provided assistance with the statistical analysis.

Serum Phosphate Concentration

Effect on Serum Ionized Calcium Concentration In Vitro

Mary Lehmann, MD, Francis Mimouni, MD

• We examined the effects of variations of serum phosphate levels on serum ionized calcium concentrations in vitro. A single donor serum sample was divided into 25 aliquots stored in tubes sealed with carbon dioxide and divided into 5 subsets of tubes. The pH was altered in 4 of the 5 subsets by adding various concentrations of hydrochloric acid or sodium hydroxide. The pH levels studied ranged from 7.09 to 7.63. The phosphate concentration was altered in each subset by adding various concentrations of a phosphate buffer. The phosphate concentrations studied ranged between 0.81 and 3.58 mmol/L. There was an inverse relationship between ionized calcium and phosphate at all pH levels studied. The ionized calcium concentration correlated inversely with pH. We suggest that in addition to factors well known to influence serum ionized calcium concentration (such as protein, bicarbonate, and pH values), serum phosphate concentration also plays an important role.

(AJDC. 1989;143:1340-1341)

Total serum calcium is present in three forms: ionized, complex, and protein bound. Ionized calcium is the active form and consists of 45% to 50% of total calcium. Complex calcium (5% to 10% of total calcium) is that calcium bound to major anions such as lactate, citrate, sulfate, bicarbonate, and phosphate. The remaining 40% to 45% of total calcium is protein bound. Several variables may affect the balance among these three forms. The effects of changes in blood pH and serum protein, bicarbonate, and magnesium concentrations have been thoroughly studied and

reported.¹⁻⁵ There are no studies of the direct effect of the serum phosphate level on serum ionized calcium concentrations, though from indirect studies it is generally believed that high serum phosphate levels may decrease serum ionized calcium concentrations.⁶ Since there might be rather wide physiologic and nonphysiologic variations of serum phosphate concentrations, particularly in childhood, we examined the effects of varying phosphate concentrations on ionized calcium concentrations in vitro. We hypothesized that, within the range of clinically encountered pH, an increasing serum phosphate concentration would lead to a decreasing ionized calcium concentration.

METHODS

A buffer solution of phosphate was prepared using 1 mol/L of monosodium acid phosphate with 1 mol/L of monobasic potassium phosphate added slowly until a pH of 7.4 was obtained. The pH was checked with a pH probe (Metrohm/Brinkmann, Westbury, NY). The 1-mol/L buffer solution was then diluted to a 0.03-mol/L solution, and its measured phosphate content was 0.81 mmol/L; the pH of the diluted solution was 7.4.

One of us (M.L.) provided the serum for study (pH 7.35); it was divided into 25 aliquots of 250 μ L each. Serum was obtained and stored in tubes sealed with 5% carbon dioxide (partial pressure of carbon dioxide in exhaled air to stabilize pH) and divided into 5 subsets of 5 tubes each. Alterations in pH were made in 4 of the 5 subsets by adding the following: 8 μ L of 0.125N hydrochloric acid (leading to a serum pH of 7.28); 17 μ L of 0.125N hydrochloric acid (leading to a serum pH of 7.09); 10 μ L of 0.125N sodium hydroxide (leading to a pH of 7.51); and 20 μ L of 0.125N sodium hydroxide (leading to a pH of 7.63). Alterations in phosphate concentration were made in each subset by adding 0, 5, 10, 15, or 20 μ L of the 0.03-mol/L phosphate buffer. Deionized water was added to each tube to reach a total volume of 290 μ L. Sam-

ples were mixed well and allowed to equilibrate overnight at 4°C.

Ionized calcium concentration and pH were assayed the following day with an ion-selective electrode (Radiometer ICA1, Radiometer Laboratories, Copenhagen, Denmark). This electrode warms the sample to 37°C (body temperature) for subsequent analysis of both pH and ionized calcium. Results of ionized calcium concentration determinations are given for the actual pH and are corrected for a pH of 7.40. The SE of measurement for this electrode is 0.012 mmol/L. Our normal range for adults is 1.20 to 1.29 mmol/L, with a coefficient of variation of 2.63%.

The serum phosphate concentration was measured (ABA 100 Analyzer, Abbott Laboratories, South Pasadena, Calif). Our normal range for adults is 0.62 to 1.17 mmol/L, with a coefficient of variation of 1.8% to 2.8%.

Statistical analysis was done by linear regression and multiple regression analyses, using the SAS package (SAS Institute, Cary, NC). $P < .05$ was considered significant.

RESULTS

The pH was used as a categorical variable for the five groups. In the Figure, we show the regression of ionized calcium concentrations on phosphate concentration at each pH level. An inverse relationship between ionized calcium concentration and phosphate concentration is noted. At all pH levels studied, the effect of phosphate concentration on ionized calcium concentration was similar: the observed slopes did not differ significantly from the theoretical common slope of -0.042 , indicating no significant deviation from parallelism of these five regression lines.

The five intercepts of ionized calcium in relation to phosphate (Figure) differed significantly from each other ($P < .05$), pointing out the effect of pH on the ionized calcium concentration. In multiple regression analysis, the ionized calcium concentration was inverse-

Plot of serum ionized calcium concentrations in relation to serum phosphate concentrations at various pH levels: top slope (circles), pH=7.09, $r = -.8378$, $P < .001$; second slope (boxes), pH=7.28, $r = -.8981$, $P < .001$; third slope (circles), pH=7.35, $r = -.9357$, $P < .001$; fourth slope (boxes), pH=7.51, $r = -.9027$, $P < .001$; and bottom slope (circles), pH=7.63, $r = -.9403$, $P < .001$.

ly correlated with pH ($R^2 = .9842$, $P < .01$); there was no significant interaction between phosphate concentration and pH.

COMMENT

From the results of this investigation, the ionized calcium concentration in vitro appears to be inversely related to both phosphate concentration and pH. The effect of increased phosphate concentration on ionized calcium concentration is similar at various pH levels between 7.09 to 7.63.

Previous studies have shown that increases in serum phosphate concentrations result in decreases in ultrafilterable calcium.⁶ However, ultrafilterable

calcium does not reflect exactly ionized calcium, since it includes both ionized calcium and complex calcium. Now, with recent technological advances in ion-selective electrodes, it is possible to measure directly, accurately, and consistently the concentration of serum ionized calcium.⁷⁻⁹

The effect of pH on serum ionized calcium concentration has been well studied in the past, and it is likely that this effect is due to the competition of hydrogen ions with ionized calcium for proteins.^{6,10}

The results of our study support the hypothesis that phosphate may bind to ionized calcium to form a complex form of calcium. The phosphate concentrations studied are frequently observed in children. Based on this in vitro study, an increase of 0.65 mmol/L of serum phosphate concentration may be associated with a decrease close to 0.25 mmol/L of serum ionized calcium. Thus, the effect on ionized calcium concentration may be clinically significant.

A limitation to our study is that it may not be possible to extrapolate from it directly to in vivo situations. In vivo, multiple other interactions may occur; a decrease in ionized calcium concentration leads to compensatory mechanisms, such as an increase in parathyroid hormone secretion and decreased calcitonin production, that may have significant effects on major target organs such as bone, kidney, and intestine.¹¹ In addition, our titration study used a blood sample obtained from a single donor. It is theoretically possible that results using serum with different protein or calcium salt concentrations would lead to quantitatively different results, though the general relationship between serum ionized calcium and phosphate concentrations should qualitatively be the same.

Thus, in addition to factors well known to influence ionized calcium con-

centration (such as protein, bicarbonate, and pH levels), serum phosphate concentration also may play an important role. Since measurement of serum ionized calcium concentration has become a reliable and clinically useful technique,⁷⁻⁹ it may be logical to substitute direct ionized calcium for total calcium measurements in clinical practice.

Serum Alkaline Phosphatase and Serum Zinc Concentrations in Preterm Infants With Rickets and Fractures

Winston W. K. Koo, MBBS, FRACP; Paul Succop, PhD; K. Michael Hambidge, MBBS, FRCP, ScD

• This study aimed to determine the longitudinal changes in serum zinc concentrations and the relationship between serum alkaline phosphatase (AP) activity and serum zinc concentrations in small preterm infants. The total serum AP and serum zinc concentrations were determined serially at 3, 6, 9, and 12 months in 72 infants with mean (\pm SEM) birth weights of 1000 ± 29 g and gestational ages of 28.6 ± 0.3 weeks. Twenty-four of 72 infants had radiographic evidence of rickets and/or fractures (R/F). In infants with R/F, group mean (\pm SEM) serum AP (371 ± 42 U/L) and serum zinc (12.5 ± 1.0 μ mol/L) concentrations were significantly higher at 3 months compared with infants in the non-R/F group (193 ± 12 U/L and 9.6 ± 0.3 μ mol/L, respectively). During the study, the serum AP concentrations decreased, and the serum zinc concentrations increased; both stabilized after 6 months. The serum AP concentrations were not related to the serum zinc concentrations. We speculate that in preterm infants, an increased bone turnover and a release of tissue (bone) zinc may contribute to the higher group mean serum AP and serum zinc concentrations at the time of diagnoses in infants with R/F compared with those infants without R/F.

(AJDC. 1989;143:1342-1345)

Alkaline phosphatase (AP) is a zinc-dependent¹ enzyme that is secreted by osteoblasts²⁻⁴, and serum AP activity appears to relate to the serum zinc concentration^{5,6} and zinc therapy.^{6,7} In normal pediatric populations, 80% to 90% of the total serum AP activity is of bone

origin.^{4,8-10} Serum AP activities are elevated in states of increased bone turnover, eg, during periods of rapid growth in infants and adolescents^{8,11,12} and in patients with rickets and/or fractures (R/F).^{2,3-12} However, serum AP activity may not be elevated in all infants with R/F,¹³⁻¹⁶ and it is not known whether the low serum AP activity in these circumstances is associated with low serum zinc concentrations. This study aimed to determine the longitudinal changes in the serum AP activity and serum zinc concentrations in small preterm infants and in the relationship between these two serum variables. We also tested the hypotheses that in infants with R/F, the serum AP activity is increased, and a low serum AP activity is associated with a low serum zinc concentration.

PATIENTS AND METHODS

Seventy-two infants with mean (\pm SEM) birth weights of 1000 ± 29 g (range, 420 to 1500 g) and gestational ages of 28.6 ± 0.3 weeks (range, 23 to 36 weeks) who had serial radiographic documentation for the presence ($n=24$) or absence ($n=48$) of skeletal abnormalities of R/F at 3-month intervals during the first year were the subjects of the present study. Radiographic abnormalities were found in 7 infants with fractures, 6 infants with rickets, and 11 infants with R/F. All active skeletal abnormalities occurred before the 6-month screening radiograph, and all these abnormalities in the infants with R/F were healed by 12 months. Details of the clinical and radiographic changes have been presented elsewhere.^{17,18} None of the investigators knew the skeletal radiographic status of the infants before their enrollment in the study. All aspects of clinical management for each infant were made by the same group of physicians during each infant's hospitalization and by the physician of the parents' choice after the infant's discharge from the hospital.

Blood collection and serum separation employed the use of stainless steel needles or butterfly needles and disposable plastic sy-

ringes. Blood and serum samples were stored in polypropylene containers. Needles, syringes, and polypropylene containers were checked at random and were free of detectable zinc. Nonfasting blood samples were collected from each infant at the mean postnatal ages of 3, 6, 9, and 12 months, ie, the same study points as the clinical and radiographic assessments. The conditions of all the infants were clinically stable at the time of assessment, and no visible hemolysis was noted in any serum samples. Serum samples were stored at -70°C and measured for AP and zinc in batches by technicians with no knowledge of the radiographic status of each infant.

The serum AP value was measured by the method of Wilkinson et al,¹⁹ by using a centrifugal analyzer. The serum AP values for normal adults range from 18 to 72 U/L at 30°C . The interassay coefficient of variation was 3.5%.

The serum zinc value was measured by using flame atomic absorption spectrophotometry with a modified spectrophotometer (Perkin-Elmer 503, Perkin-Elmer Corp, Norwalk, Conn) that was fitted with a deuterium arc background correction and an auto-sampling system (AS3). For analysis, duplicate samples of 150- μ L aliquots of serum were transferred to small circular quartz dishes for overnight ashing in a low-temperature asher (LFE Corp, Waltham, Mass). The ash samples were dissolved with 150 μ L of 0.1N hydrochloride. A 100- μ L aliquot of the dissolved ash was diluted with 500 μ L of 6% butanol in 0.1N hydrochloric acid.^{20,21} Standards also were made up in 6% butanol in 0.1N hydrochloric acid. The interassay coefficient of variation was 1.7%. The detection limit for this assay was 0.6 μ mol/L. The normal adult reference range is from 9.2 to 15.4 μ mol/L (1 μ g/dL = 0.154 μ mol/L). The value obtained for the National Bureau of Standards bovine liver (certified value = 130 ± 13 μ g [mean \pm SD] of zinc per gram of dry weight), by using the same analytical techniques, was 129 ± 3 μ g of zinc per gram of dry weight.

The nutrient intakes during infancy¹⁸ were similar between the groups, except that infants with R/F received parenteral nutrition

†Radiographic R/F in VLBW infants: A = present and B = absent.

‡Initial values were higher and rate of decline was faster in infants with R/F ($P < .001$, respectively, by random coefficient regression analyses). No significant difference between groups after 6 months.

§Initial values were higher and rate of increase was slower in infants with R/F ($P < .001$, respectively, by random coefficient regression analyses). No significant difference between groups at 9 months.

for longer periods (40 \pm 11 days vs 16 \pm 3 days [mean \pm SEM], $P < .001$) and they received preterm infant formula for longer periods (23 \pm 7 days vs 4 \pm 1 days [mean \pm SEM], $P < .001$). Standard parenteral nutrition delivers 300 μ g of elemental zinc per kilogram per day. Other components of standard parenteral nutrition were used as previously described.²²

At one of the blood sampling times, two infants received total parenteral nutrition for temporary feeding intolerance. All infants received enteral feedings when the blood samples were taken at other times. Enteral nutrients included mother's milk or 2814 kJ/L of standard cow's milk formula. Mother's milk was used for 9 of 24 infants in the R/F group and for 22 of 48 infants in the non-R/F group. Vitamin D-fortified whole cow's milk was introduced in 4 infants (1 in the R/F group) by 9 months and in 15 infants (4 in the R/F group) by 12 months. An increased enteral zinc intake in the form of preterm infant formula (Similac Special Care, Ross Laboratories, Columbus, Ohio) or powdered human milk fortifier (Mead Johnson & Co, Evansville, Ind) was given to 30 infants (17 in the R/F group) for 1 to 183 days (median, 26 days). Soy formula (Isomil, Ross Laboratories) was given to 3 infants (1 in the R/F group) for more than 3 months, and it was given to another 6 infants (4 in the R/F group) intermittently as clinically indicated. Protein hydrolysate formula (Pregestimil, Mead Johnson Co) was given to 6 infants (1 in the R/F group) for 6 months or greater.

This study was approved by the Review Board for Human Investigation, and written informed consent was obtained from a parent of each subject.

STATISTICAL METHODS

For replicated measurements, the natural logarithm of each serum variable was used to normalize the statistical distributions. In addition, the postnatal age of each infant at measurement was transformed to its natural logarithm to allow for deviations from linearity in the changes of serum variables over time. The serial changes with age for each variable were estimated for each infant by random coefficient regression analyses.^{23,24}

The serial changes of each serum variable in infants with R/F were compared with those in infants without R/F in a linear regression model, controlling for any significant potential covariates (confounding variables). The strategy of backward elimination was used to select the potential covariates that significantly affected the serial changes in the serum AP or serum zinc concentrations. Only the significant potential covariates were retained in the statistical model in the final analysis. The covariates used were gender, birth weight, gestational age, body weight, and length at each study, since these factors have been reported to affect the serum AP^{8,9,11,25} or serum zinc^{26,27} concentrations. The amount of zinc delivered from parenteral nutrition, preterm infant formula, and powdered human milk fortifier is greater than that from human milk or standard formula²⁸; thus, the durations for which these nutrients were received by the infants also were entered as potential covariates in the statistical model.

Statistical analyses were performed by using the CLINFO program of the National Institutes of Health, at the General Clinical Research Center of the University of Cincinnati (Ohio), and the Computer Center main-

frame computer (Amdahl 5880) at the University of Cincinnati. A P value of .05 was used to judge the significance of each estimated parameter in all statistical tests.

RESULTS

The serial changes in the serum AP and serum zinc concentrations are shown in the Table. Owing to the blood volume limitations, the serum AP value was measured in 72 infants (24 with R/F), and the serum zinc value was measured in 49 infants (17 with R/F). The serum zinc measurements were available only for infants who were receiving enteral feedings; 3 infants with R/F and 1 infant without R/F were receiving a premature infant formula on the day of blood sampling for a total of four and one occasions, respectively. The nutrient intake was otherwise similar between the groups.

For the serum AP values, body weight was the only significant covariate ($P < .001$). The mean initial serum AP values were elevated in both groups compared with the adult norms and were significantly higher in the R/F group. The serial serum AP values decreased in both groups, but the rate of decrease in the serum AP values was significantly greater in infants with R/F ($P < .001$). There was no significant difference in the serum AP values between the groups after the second measurement at 6 months. One infant with persistent cholestatic jaundice, presumably from the prolonged use of par-

enteral nutrition, had one simultaneous serum AP and serum zinc measurement. The values were 152 U/L and 13.9 $\mu\text{mol/L}$, respectively.

For the serum zinc concentrations, none of the potential covariates that were entered into the regression models were statistically significant. The initial serum zinc concentrations were significantly higher in the R/F group. The serial serum zinc concentrations increased in both groups, but the rate of increase in the serum zinc concentrations was significantly greater in infants without R/F ($P < .001$). The difference in the mean serum zinc concentrations between the groups became smaller with increasing age.

There was a weak positive correlation ($r = .23$) between the estimated serial changes in serum AP and serum zinc concentrations that was not statistically significant ($P = .18$).

COMMENT

The normal range of serum AP concentrations for very-low-birth-weight infants has not been well defined²⁹ because most reports have included few subjects with simultaneous serum AP data and radiographic documentation of skeletal status. To our knowledge, this is the only study with serial radiographic documentation through the active phase to complete healing of the skeletal lesions in very-low-birth-weight infants with simultaneous serum AP and serum zinc measurements.

The serum AP activity, expressed as a proportion of the adult reference range, minimizes the difficulty in interpreting data from the methodological differences in the serum AP measurement.^{12,29} In the present study, the group mean serum AP activity at the time of the diagnosis of R/F was approximately 5.2 times the upper reference range for normal adults in our laboratory and was similar to that reported by others.¹² This was significantly higher than the group mean serum AP activity in the non-R/F group and was consistent with a further increase in bone turnover from R/F that was superimposed on the rapid growth of these small preterm infants. The decline in the serum AP activities with increasing age and the similarity of serum AP activities between the groups during the second half of

infancy were consistent with radiographic healing of R/F. However, the serum AP activity at 1 year in both groups remained higher than the adult reference range by 1.5- to 1.9-fold. This is consistent with the continued skeletal growth and bone mineralization in these infants.

It has been reported that an absence of an increased serum AP activity is associated with hypozincemia and hypomagnesemia,⁶ and infants with chronic diarrhea who are receiving inadequate zinc replacement may have low serum AP and serum zinc concentrations.⁶ The elevation of serum zinc concentrations on zinc replacement is associated with an elevation of the serum AP activity.^{6,7} In infants with rickets, there has been no documentation as to whether a low serum zinc concentration occurs in association with a normal or low serum AP activity.¹²⁻¹⁶ In the present study, absolute concentrations and changes in the serum AP values were not significantly correlated with the serum zinc concentrations; thus, the low serum AP activity in some infants with R/F could not be accounted for by low serum zinc concentrations. However, this study was not designed to measure zinc status, and we cannot rule out the possibility of a relatively zinc-deficient state in some of our infants who underwent studies.

It is known that the major source of the total serum AP activity in infants and children is of bone origin.^{4,8-10} All but two patients in this study had not received parenteral nutrition for many weeks before the first blood sampling, which may account for the low rate of persistent jaundice. Hepatic AP, therefore, is unlikely to account for a large proportion of the total serum AP activity. The activities of all isozymes of AP are zinc dependent and should not affect the determination of the relationship between the total serum AP activities and the serum zinc concentrations in this study.

The serum zinc concentrations, on initial sampling at 3 months, were higher in infants with R/F. It is theoretically possible that a greater zinc intake from parenteral nutrition and zinc-fortified milk intake before the blood sampling may have accounted for the higher serum zinc concentrations in the R/F group. However, an increased zinc in-

take in infants from both groups were controlled in our statistical analyses and were demonstrated to have no significant influence on the serum zinc concentrations. The release of tissue (bone) zinc from the increased bone turnover in rapidly growing infants, particularly those with R/F, may be responsible for the higher serum zinc concentrations. This finding is supported by the report of higher serum concentrations of 1,25-dihydroxyvitamin D in small preterm infants with R/F compared with those infants without R/F³⁰ which presumably results in increased osteoblastic activity and bone turn-over.^{3,31}

The serum zinc concentrations in our infants who underwent studies increased with increasing postnatal age. This finding is consistent with the changes in the serum zinc concentrations for term infants.³² The concentrations of serum zinc in our infants who underwent studies also were similar to those reported for term infants.^{32,33} Consistent with the healing of R/F and presumably a decreased release of tissue zinc, in particular that from bone, the serum zinc concentrations were similar in both groups after 6 months.

In conclusion, we have demonstrated that group mean serum AP and serum zinc concentrations are higher in infants at the time of the diagnosis of R/F. There were no correlations for the serum AP and serum zinc concentrations. We suggest that an increased serum AP value is consistent with an increased bone turnover. The higher the serum zinc values in infants with R/F at 3 and 6 months presumably are consistent with the release of tissue zinc from the increased bone turnover. In the present study, with increasing postnatal age and healing of R/F, serum AP and serum zinc concentrations became stabilized and were similar in very-low-birth-weight infants, regardless of their previous radiographic status with respect to R/F.

CORRECTION

Incorrect Order of Authors' Names.—In the letter to the editor entitled "Fructose-1,6-diphosphatase Deficiency: A 20-Year Follow-up," published in the February 1989 issue of *AJDC* (1989;143:140-142), the authors' names in the signature on page 141 were listed in the incorrect order. The order should have been as follows: Orly N. Elpeleg, MD; Varda Barash, PhD; Haggit Hurvitz, MD; and David Branski, MD.

Bone Mineral Content in Black and White Children 1 to 6 Years of Age

Early Appearance of Race and Sex Differences

Jie-Ying Li, MD; Bonny L. Specker, PhD; Mona L. Ho, MS; Reginald C. Tsang, MBBS

• Bone mineral content was determined in 131 children, 1 to 6 years of age, in a prospectively designed cross-sectional study. Using multiple linear regression analysis to control for individual factors, bone mineral content was higher in black children compared with white children, was lower among female children compared with male children, increased with age, and increased with weight. (AJDC. 1989;143:1346-1349)

Measurement of bone mineral content (BMC) in the forearm by photon absorptiometry is a simple and precise method to study the amount of mineral in bone.^{1,2} It has been widely used in normal subjects and in patients with metabolic bone disorders. In childhood, BMC increases significantly with age.^{3,4} Differences by sex also have been studied; in one study, male infants had higher BMC than female infants.⁵ In another study, Specker and coworkers⁴ demonstrated that among white children, boys and girls have similar BMC from 1 to 4 years of age, but girls have significantly lower BMC at 5 to 6 years of age. However, there is currently a lack of normative data of BMC in healthy black children 1 to 6 years of age. Available data indicate that bone mass is increased in black, as compared with white, adolescents and adults^{6,7} and that skeletal development (as measured by appearance of ossification centers) of black children (aged 1 to 7 years old) is advanced in comparison with that of white children.⁸ Racial differences in BMC, however, have not been exam-

ined in early childhood. We hypothesized, in this prospective study of 131 children 1 to 6 years of age, that (1) black children would have higher BMC compared with white children; (2) BMC would be lower in female children compared with male children; and (3) BMC would increase with increasing age.

SUBJECTS AND METHODS

Subjects

Seventy-eight black and 53 white children 1 to 6 years of age were recruited for this prospectively designed cross-sectional study from the well-child clinic at the Children's Hospital Medical Center, Cincinnati, Ohio, from December 1987 to March 1988. This study population is distinct from a previously studied group of predominantly white children who were recruited from private pediatric practices and examined for BMC.⁴ Information on gestational age, sex, race, date of birth, history of breast-feeding, and current use of vitamin supplements was obtained from the parent. All children were term at birth and none of them had known major congenital abnormalities, bone disorders, or significant gastrointestinal disease and renal disease. All children were between the fifth and 95th percentile on the Boston growth curves.⁹ No blood samples were obtained for study.

Multiple linear regression techniques were used to determine differences between groups and correlation among variables. The partial correlation coefficients for each of the significant factors in the regression analysis are given. The partial correlation is the amount of variability explained by that factor after the other factors are included in the model. The protocol was approved by the Institutional Review Board of the Cincinnati Children's Hospital Medical Center and parental informed consent was obtained.

Photon Absorptiometry

The BMC and bone width (BW) were measured by a direct photon absorptiometer (Lunar Radiation Inc, Madison, Wis). A collimated, 2-mm-diameter photon beam from

low-activity monochromatic radionuclide source (iodine 125) passed beneath the on third distal radius (shaft) of the left forearm. The detection site was located by external measurement. A collimated scintillation detector placed over the arm was equipped with a mechanism to allow for simultaneous movement of the collimated detector and ¹²⁵I source, with a scan speed of 0.5 mm per second in children under 3 years of age and 1 mm per second in children over 3 years of age. The child's forearm was placed in a holding device and surrounded by a water bag to maintain constant thickness across the measuring path. At least three scans were obtained for each child and the mean value was obtained. The attenuation of detected counts is proportional to the mass (grams per centimeter) of mineral in the scan path; B is proportional to the length of the scan path. The accuracy of the photon absorptiometer when compared with ashed bones for BMC is high (error, 2% to 4%) with a high precision (error, 2%).¹ Our coefficient of variation for phantom standards is less than 1.5%.

RESULTS

Seventy-eight children (59.5%) were black, and 48.9% of the children were male. Thirty-three percent of children were receiving vitamin supplements containing vitamin D at the time of the study. The average age of those receiving vitamins was 38 months. Twenty-one (16%) of the children had been breast-fed, with an average weaning age of 28 weeks. There were no racial differences in the percent of children currently receiving vitamin supplements (30% of black children and 38% of white children, $P = .4$) or previous breast-fed (13% of black children and 25% of white children, $P = .09$). Mean BMC and BW were not different between children taking vitamin supplements or not, even after controlling for other variables significantly associated

*Data were analyzed using a multiple general linear model that statistically controls for the influence of other factors on BMC. Race ($P < .001$), sex ($P = .02$), age ($P < .001$), and weight ($P < .001$) were found to be independent predictors of BMC. Data are presented in 2-year age groupings for reference.

†The number of subjects was 18 for this measurement.

with BMC. In the multiple-regression model presented below, children who were previously breast-fed had a higher BMC than children not previously breast-fed ($P = .03$). However, one black male child, 6.7 years of age and previously breast-fed, had a high BMC (0.559 g/cm). When he was omitted from the analysis, the only difference in the findings was that the relationship between history of breast-feeding and BMC was no longer statistically significant. The results presented below include this data point, but history of breast-feeding has not been included in the final statistical model due to the questionable relationship resulting from inclusion of data on one child.

The age, sex, and race distributions, as well as the mean BMC, BW, BMC-to-BW ratio, weight, and height, are given in the Table. Two-year age groupings were used in the Table due to the small numbers of children in each race and sex

group if categorized into 1-year age groups. Female children weighed less than male children ($P = .02$) after adjusting for age. There was no difference in weight between black and white children.

Age, sex, race, and weight were found to be independently associated with BMC (overall $R^2 = .771$). The BMC was higher in black children compared with white children (partial $R^2 = .114$, $P < .001$), was lower in female children (partial $R^2 = .044$, $P = .02$), and increased with age (partial $R^2 = .110$, $P < .001$) and weight (partial $R^2 = .193$, $P < .001$). We had previously found a smaller increase in BMC with age in female children compared with male children⁴; this relationship, tested by the interaction of age and sex, was not observed in the current study, and female children had a lower BMC at all ages compared with male children (Figure).

Bone width increased with increasing weight (partial $R^2 = .343$, $P < .001$) and was greater in black children compared with white children (partial $R^2 = .032$, $P = .04$). Bone width was greater in older compared with younger children (in univariate analysis); however, weight was a stronger predictor of width than age and age was not included in the final model. Results for the ratio of BMC to BW were similar to those obtained for BMC.

COMMENT

Photon absorptiometry has been shown to be a precise and accurate method for determining BMC in both adults and infants. It also has made a great contribution to the understanding of clinical factors influencing bone mineralization. In children, the method has been used to (1) determine the effects of various factors on BMC, such as sex,^{8,9} age,^{4,10,11} and nutrition,^{6,12} and (2) quantify effects of diseases on BMC, especially in bone disorders.^{13,14}

In this study, we demonstrated that BMC was not associated with history of breast-feeding or current use of vitamin supplements. Breast-feeding has been associated with BMC that is lower than that of formula-fed infants during the first 6 months,¹⁵ but there is little information on the influence of early breast-feeding on BMC in later childhood. The small percent of children who had been breast-fed had similar BMC to those children who had not been breast-fed.

To our knowledge, normative data of BMC in black children are not available. In the present study, black children 1 to 6 years of age had higher mean BMC than white children. In earlier studies, black infants and children have been found to have advanced skeletal development, as measured by the presence of ossification centers, compared with white infants and children.⁸ It has been suggested that the higher bone mass in blacks is due to a larger body mass, which results in increased strain on the skeleton, which would then stimulate bone formation.¹⁶ However, black adult women have 10% to 20% greater total body calcium and phosphorus compared with white women even after adjusting for body weight.⁷ Our current findings support a race difference in BMC independent of body weight. The reason for

Bone mineral content by year of age for each race and sex. Bone mineral content: was higher in black (top) compared with white (bottom) children ($P < .001$), increased with increasing age ($P < .001$), and was lower in female (plus sign) compared with male (asterisk) children ($P = .03$). Increased body weight also was found to be associated with higher bone mineral content ($P < .001$) independent of the other factors.

this difference is not clear since factors other than genetic may influence BMC (ie, diet).

White female children of varying ages have been found to have lower BMC compared with male children.^{3,6} In the current study, there was significantly lower BMC in female children compared with male children 1 to 6 years of age. In our previous study of BMC in white children from private pediatric practices,

we observed a lower BMC among female children compared with male children only after 4 years of age.⁴ The reason for sex differences in BMC is unclear but does not appear to be related to differences in body weight since in our analysis sex differences were still apparent after statistically controlling for the influence of weight.

In the present study, BMC increased with increasing age. Increases in BMC

with increasing age have been demonstrated in children 1 to 14 years of age,^{3,4} and our study is consistent with these reports. Weight also was found to have an independent influence on BMC and may be due to the increased strain on the skeleton resulting in increased bone formation.¹⁷

Findings concerning the ratio of BMC to BW were similar to those of BMC. It has been suggested that the ratio of BMC to BW reduces variation and would be of more value in determining the difference between an individual and the normal population, whereas BMC is a better measurement to follow in an individual for bone mineral changes.¹⁸ However, several studies demonstrated that a BMC-to-BW ratio is not a more sensitive indicator than BMC.^{13,18,19}

In view of the current findings, race- and sex-specific BMC norms would be helpful when BMC is used as a tool for diagnosing disordered bone mineralization. Anecdotally, rickets appears to be identified in the United States more in black than white infants and children^{20,22}; it might be important to recognize that norms for BMC are different between races when assessing BMC in such infants. For example, black infants with rickets may have BMC that appears normal by white infant studies, but may be low by black infant norms.

In summary, differences in BMC by race, sex, age, and weight were observed; BMC was higher in black compared with white children, was lower in female than in male children, and increased with age and weight.

nosis of left external otitis. The physical examination results were normal except for an extremely narrowed left external auditory canal. The narrow lumen was engulfed by bony overgrowth, and no local edema or signs of inflammation were seen. Audiologic evaluation demonstrated a moderate conductive hearing loss. A computed tomographic scan of the region was performed (Figure).

Denouement and Discussion

Monostotic Fibrous Dysplasia of the Temporal Bone

Computed tomographic scan demonstrating narrowing of the left external auditory canal caused by an expansile bone lesion of the temporal bone (curved arrow). The regional bone was characterized by a "ground-glass" appearance. A small cholesteatoma is located between the tympanic membrane and the bony lesion (black arrow).

The patient underwent surgical exploration of the ear. The nearly obliterated lumen was widened, and the canal was cleaned of cholesteatoma debris found trapped between the eardrum and the narrowed bony isthmus. Histologic sections confirmed the diagnosis of fibrous dysplasia.

Fibrous dysplasia is a congenital, locally circumscribed nondifferentiation of bone-forming mesenchyme. The lesion is characterized histologically by a proliferation of fibrous tissue and scattered trabeculae of immature bone. The disease has three clinical forms: (1) monostotic, which is isolated to one bone; (2) polyostotic, which affects two or more bones; and (3) Albright's syndrome, which is a polyostotic form associated with abnormal skin pigmentation, precocious puberty, and other nonskeletal manifestations. The disease usually becomes manifest in late childhood when lesion growth accelerates rapidly, only to become quiescent, in most in-

stances, after puberty. This uncommon disease rarely involves the temporal bone.^{1,2}

The roentgenographic features of fibrous dysplasia are usually characteristic and in a series of 46 consecutive cases of fibrous dysplasia of the craniofacial skeleton were found in each case to correlate accurately with the pathologic analysis.³ The roentgenographic examination reflects the morphologic nature of the disease and the results vary with the amount of fibrosis and calcification present. Areas of fibrosis and cyst formation produce radiolucency, whereas areas of new bone formation demonstrate increased density. In many instances, local expansion in the temporal bone is seen associated with either sclerosis or a uniform "ground-glass" appearance.^{1,2} Occasionally, areas of radiolucency and cortical thinning are seen and constriction or even obliteration of the external auditory canal can be regularly demonstrated. Computed

tomographic scanning provides good detail of the extent of the disease. An accurate assessment of the degree of middle-ear involvement and of the presence of associated cholesteatoma can be made.⁴

In our case the computed tomographic scan demonstrated the extent of the disease and the existence of a cholesteatoma. The combined findings of roentgenograms and computed tomography established the diagnosis of fibrous dysplasia, which was later confirmed by pathologic study.

Denouement and Discussion

Morphea

Fig 1.—Hyperpigmented lesions and facial atrophy.

Fig 2.—Cicatricial alopecia.

Fig 3.—Multiple hyperpigmented lesions on the trunk.

Manifestations

Morphea, also called linear scleroderma, is a form of scleroderma that has a patchy focal distribution. Initially, the lesions are slightly erythematous and edematous or may have an atrophic, shiny appearance. Subsequently, they appear as ivory-colored indurated plaques with violaceous borders. The lesions usually first appear on the trunk and spread to the limbs. Scarring and fibrosis occur, which can lead to contractures and apparent shortening of limbs.

The disease may progress for years or arrest after several months of activity. In dark-skinned individuals, the scars may become hyperpigmented, and in others, the atrophic areas may become hypopigmented. Lesions on the scalp may produce cicatricial alopecia, and facial hemiatrophy occurs

due to sclerosis of the facial muscles. Erosion of the underlying bone may also occur.

Microscopic examination reveals sclerosis associated with varying degrees of inflammation involving the dermis and occasionally extending to the subcutaneous tissue and panniculus. Eosinophilia, elevated sedimentation rate, and low complement may be present. Antinuclear antibodies and rheumatoid factor are present in 5% to 15% of the cases.

Causative Factors

Trauma and drugs such as valproic acid have been reported as possible causative factors. Immunologic or vascular injury and altered collagen metabolism are suggested mechanisms. There does not appear to be any genetic predisposition.

Treatment

No effective treatment is presently available. A variety of medications have been used, such as D-penicillamine, corticosteroids, salicylates, chelating agents, chloroquine phosphate, and radiation, without any definite benefit. The disease usually follows a slow, indolent course, and the cicatricial process gradually becomes passive. Prognosis for life is usually good, unless there is systemic involvement, which is unusual.

AVEENO® Bath Breaks the Itch-Scratch Cycle in Childhood Pruritus

When children itch, they scratch. And secondary infections can follow in excoriated areas. Aveeno Bath contains powder-fine colloidal oatmeal, a naturally effective antipruritic, to soothe the itch and help stop the scratch.

Aveeno provides adjunctive therapy to soothe, cleanse and refresh delicate skin in a wide range of pruritic conditions:

Eczema	Chicken Pox
Atopic Dermatitis	Prickly Heat
Dry Skin	Poison Ivy/Oak
Diaper Rash	Sunburn

Whatever the itch, recommend Aveeno Bath.

Aveeno Bath Regular Formula
Active Ingredient: Colloidal oatmeal, 100%

Aveeno Bath Oilated Formula (for Dry Skin)

Active Ingredient:
Colloidal oatmeal, 43%

Also contains a specially formulated emollient system

*Recommend Aveeno for
Soothing Pediatric Skin Care*

Early Diagnosis of Spastic Diplegia, Spastic Hemiplegia, and Quadriplegia

Susan R. Harris, PhD, PT

• A retrospective study examined early neurodevelopmental behaviors of children with spastic diplegia, spastic hemiplegia, and quadriplegia (spastic, athetoid, or mixed) who had been followed up longitudinally in a high-risk infant follow-up clinic. Compared with peers with normal outcomes, children with all three types of cerebral palsy had significantly lower scores on the Bayley Mental Scale at 4 months of age; children with hemiplegia and quadriplegia also scored significantly lower on the Bayley Motor Scale. On the Movement Assessment of Infants at 4 months of age, the children with hemiplegia and quadriplegia showed significantly higher risk scores than the nonhandicapped group. The Movement Assessment of Infants was more than three times as sensitive as the Bayley Motor Scale in detecting motor abnormalities in 4-month-old infants with diplegia and more than twice as sensitive in detecting early abnormalities of hemiplegia. At 1 year of age, however, the Bayley Motor Scale was extremely sensitive in picking up motor deficits in children with all three types of cerebral palsy.

(AJDC. 1989;143:1356-1360)

Although controversy continues about whether the prevalence of cerebral palsy (CP) is increasing among very-low-birth-weight infants, Kitchen and colleagues¹ maintain that the prevalence is "unacceptably high," with a rate of 12.5% of spastic CP among 2-year-old survivors at their hospital. Diagnosis of CP during infancy is extremely difficult, particularly in mild to moderate cases,^{2,3} which accounted for approxi-

mately two thirds of the children in the recent study by Kitchen et al.¹ Definitive diagnosis during infancy of three common types of CP, spastic diplegia, spastic hemiplegia, and quadriplegia (spastic, athetoid, or mixed), has not, to my knowledge, been reported in the literature. The purpose of this study was to identify retrospectively a variety of developmental markers that could serve to differentiate these three types of CP during the first year of life. Subjects were children who were part of a prospective, longitudinal high-risk infant follow-up project at the University of Washington, Seattle, from 1976 to 1985.

Hypotheses in this study were as follows: (1) Children with spastic diplegia, spastic hemiplegia, and quadriplegia differed significantly from nonhandicapped (NH) children on the Bayley Mental and Motor Scales.⁴ (2) Children with spastic diplegia, spastic hemiplegia, and quadriplegia differed significantly from NH children on categorical risk scores and total risk scores of the Movement Assessment of Infants (MAI).⁵ (3) The Bayley Motor Scale was sensitive to early diagnosis of spastic diplegia, spastic hemiplegia, and quadriplegia at 4 months' and 12 months' corrected ages. (4) The MAI was sensitive to early diagnosis of spastic diplegia, spastic hemiplegia, and quadriplegia at 4 months' corrected age.

In addition, the average ages for definitive diagnoses of each of these types of CP were examined. Recent articles have suggested that reliable diagnosis of spastic diplegia does not occur until 18 to 24 months of age in the United States,⁶ and that for children with congenital hemiplegia, the average age of referral for developmental evaluation at a center in England was 22 months.⁸

METHODS

Subjects and Methods

The original sample consisted of 399 infants who had been evaluated initially between 1976 and 1981 in the University of Washington's Neonatal Intensive Care Unit Followup Clinic. Entry criteria included birth weight of 1500 g or less, a history of idiopathic respiratory distress syndrome, or any other clinical condition posing a high risk for abnormal development, such as central nervous system infection or insult.

Infants were scheduled for evaluation at the following ages (corrected for prematurity): 4, 12, 24, 36, 54, 72, and 96 months. There were 399 infants who were evaluated initially between 3 months 15 days' corrected age and 4 months 14 days' corrected age; 229 (57.4%) of these children were followed up at least through the 36-month corrected-age visit. Due to reported difficulties in reliably diagnosing CP at 1 year of age⁹ and sometimes even later,^{5,8} it was decided that subject selection would be limited to those children for whom both medical and psychological follow-up data were available at 3 years of age or older.

Review of the follow-up records showed that approximately 80% of the infants unavailable for follow-up appeared normal at their last visit with the other 20% having been labeled as either questionable or abnormal.⁴ These findings are similar to those of Aylward and colleagues,¹⁰ which suggested that handicapped infants are no more likely to continue in follow-up than infants who are developing normally.

Assessment Tools

At their initial follow-up visit at 4 months' corrected age, infants were assessed by clinic physical therapists using the Mental and Motor Scales of the Bayley Scales of Infant Development, a standardized, norm-referenced tool, and the MAI, a neuromotor assessment tool that has been shown to be both reliable^{11,12} and valid¹³ in the evaluation of high-risk infants. The MAI consists of 65 items divided across four categories: muscle tone, primitive reflexes, automatic reactions, and

volitional movement. Based on a 4-month profile developed from a small sample of infants,⁷ 48 of the 65 items can be scored as either "risk" or "no risk." Categorical risk scores are then derived for each of the four categories and are ultimately summed to attain a total risk score.

A variety of outcome measures were administered at the follow-up visits between 36 and 96 months of age. Developmental pediatricians assessed the children using the Denver Developmental Screening Test¹⁴ and a nonstandardized neurological examination that evaluated muscle tone and motor and speech development. Developmental psychologists used various standardized psychometric tests according to the child's corrected age: the Stanford-Binet Intelligence Scale,¹⁵ the Wechsler Preschool and Primary Scale of Intelligence,¹⁶ the Wechsler Intelligence Scale for Children-Revised,¹⁷ and the Peabody Picture Vocabulary Test.¹⁸ At the 54-month visit, occupational therapists assessed the children's motor development and coordination using an assessment protocol that included the gross motor portion of the Peabody Developmental Scales,¹⁹ the Frostig Eye-Motor Coordination subtest,²⁰ and portions of the Southern California Sensory Integration Test.²¹ All examiners were aware of the child's previous developmental test scores; no attempt was made to blind them to the child's developmental history.

Outcome Groups

Chart reviews were conducted for the 229 children who were followed up to at least the 36-month-old visit. Based on scores on standardized tests as well as medical diagnoses provided by the pediatricians when appropriate, the following three groups were defined: CP ($n=36$), developmental delay ($n=75$), and NH ($n=118$). Children in the CP group were further divided into three diagnostic categories: spastic diplegia ($n=14$), spastic hemiplegia ($n=11$), and quadriplegia ($n=11$), which included spastic, athetoid, and mixed (spastic/athetoid) cases. In addition to the type of CP, the severity was determined by the developmental pediatricians based on the following criteria: (1) mild was defined as no use of mechanical aids for ambulation, the child functions without obvious impairment; (2) moderate was defined as no need for mechanical aids for ambulation, but the child functions with obvious impairment; (3) severe was defined as the child ambulates only with mechanical aids; and (4) profound was defined as no ambulation.

Children in the group labeled "developmental delay" had a mixture of deficits ranging from mild motor delays or expressive language disorders to moderate mental retardation. Children in the NH group were those who performed within normal limits on

all developmental tests and who were deemed "normally developing" by the pediatricians at their latest follow-up visit.

Data Analysis

The first two hypotheses were examined by performing Student's t tests between each of the CP categories (spastic diplegia, spastic hemiplegia, and quadriplegia) and the NH group. The final two hypotheses were addressed by calculating the sensitivity of each tool in correctly identifying motor abnormalities at 4 months' (Bayley Motor Scale and MAI) and at 12 months' (Bayley Motor Scale) corrected ages. Also calculated were the mean ages and ranges for diagnoses of spastic diplegia, spastic hemiplegia, and quadriplegia.

RESULTS

Although the children with spastic diplegia were significantly smaller at birth than their NH counterparts, they were not significantly younger (Table 1). Whereas the children with spastic hemiplegia tended also to be smaller and younger than the children in the NH group, neither of these differences was significant. In contrast, the children with quadriplegia were remarkably similar in mean birth weight and gestational age to the NH group. With the exception of one infant in the hemiplegic group and one infant in the quadriplegic group, all of the other infants were born at less than 37 weeks' gestation (Table 1).

On the Bayley Scales of Infant Development, the 4-month-old children with spastic diplegia scored significantly lower than their NH age-matched counterparts on the Bayley Mental Scale (Mental Developmental Index [MDI]) but not on the Bayley Motor Scale (Psychomotor Developmental Index [PDI]). The mean scores for the MDI and PDI for the children with spastic diplegia were well within normal limits

(mean = 100), although the SD for the PDI was greater than the normative SD of 16. The 4-month-old children with spastic hemiplegia scored significantly lower than the NH group on both the MDI and the PDI; however, both mean scores for these developmental indexes were well within normal limits. In contrast, the children with quadriplegia scored significantly below the mean for both the mental and motor scales and were significantly different from their NH peers.

These differences can be accounted for, in part, by the differences in severity levels among the three groups. Whereas 64% of the children with diplegia were judged to be mild or mild to moderate in involvement and 82% of the group with hemiplegia were similarly rated, only 27% of the children with quadriplegia were so rated. These disparities suggest that it is the relative severity of involvement as well as the type of CP that appears to affect performance on the Bayley Scales (Table 2).

On the MAI at 4 months' corrected age, there were no significant differences between the children with spastic diplegia and the children in the NH group on any of the four categorical risk scores or on the total risk score. However, the children with spastic hemiplegia differed significantly from the NH children ($P<.05$) on three of the five scores: the categorical risk scores for automatic reactions and volitional movement and the total risk score (Table 3).

The sensitivity of the Bayley Motor Scale at 4 and 12 months' corrected ages was assessed by dividing the number of correctly identified abnormal cases at each age into the total number of abnormal cases and then multiplying this fraction by 100.²² For the Bayley Motor Scale, an abnormal score would be a

PDI of less than 84 (Table 4). The specificity of the Bayley Motor Scale at 4 months of age or its ability to correctly identify infants as normal who subsequently were judged to be normal at 36 to 96 months of age has been reported previously as 94.9%.²³

The sensitivity rate of the Bayley Motor Scale improved markedly at 12 months of age, particularly for the diplegic and hemiplegic groups. This dramatic improvement in sensitivity may have been due to the evolving clinical nature of CP rather than to deficiencies in the test at earlier ages.

The MAI was administered only at 4 months' corrected age. According to the MAI manual, total risk scores of 0 to 7 are considered "low risk," with scores of 8 to 12 being "at risk," and scores equal to or greater than 13 identified as "high risk" for motor problems.⁷ To examine the sensitivity of the MAI total risk score at 4 months of age, the number of correctly identified "at-risk" and "high-risk" infants (scores ≥ 8) were divided into the total number of infants who were subsequently diagnosed with diplegia, hemiplegia, or quadriplegia (Table 5). The specificity of the MAI at 4 months of age was 62.7%, which suggests that more than one third of the children who were subsequently judged to be NH had either suspect or abnormal total risk scores at 4 months of age.²³

The mean age at diagnosis for infants with spastic diplegia was 12.58 months (range, 4 to 30 months); approximately two thirds of these infants' conditions were rated mild or mild to moderate in severity. For the children with spastic hemiplegia, 82% of whom were labeled mild or mild to moderate, the average age of diagnosis was 21 months, with a range from 4 to 54 months of age. In contrast, the mean age for diagnosis of the infants with quadriplegia was 4.91 months, with a range from 1 to 10.5 months of age. This is not surprising since about 73% of the infants in this group were given severity ratings ranging from moderate to profound.

COMMENT

The first hypothesis was partially supported in that children in all three CP categories differed significantly from the children in the NH group with regard to scores on the Bayley Mental

Scale. Children with hemiplegia and quadriplegia differed significantly from the NH group on the Bayley Motor Scale as well. Although the children with spastic diplegia had lower Bayley Motor scores than the NH children, this difference failed to reach significance at the .05 level. The lack of a significant difference may be due to the relatively small sample size.

Although both the mean MDI and PDI scores for the children with hemiplegia were significantly below those for the NH children, they were both within the normal range. In fact, only 3 of the 11 children scored below the normal ranges on the mental and motor scales. Five children in this group showed cognitive delays (IQ < 85) at their latest follow-up visits as did 5 children in the spastic diplegic group.

Both the mean MDI and PDI scores were well below the normal ranges for the children with quadriplegia at both 4 and 12 months' corrected ages and significantly different from those of their NH age-matched counterparts. At 12 months of age, all 9 children tested scored below 84 on both the MDI and the PDI. However, 3 of the 11 children had IQ scores within normal limits at their latest follow-up visits. Since the Bayley Mental Scale involves many fine motor items, it is not surprising that the children's MDIs were compromised by their upper-extremity motor handicap. Clinicians should use caution when using the Bayley Mental Scale for children with upper-extremity motor handicaps since it may not provide an accurate reflection of cognitive skills.

The second hypothesis was supported in part for children with hemiplegia and

in its entirety for children with quadriplegia. The children with hemiplegia differed from the NH group on the MAI total risk score and two of the four categorical risk scores. Children in the quadriplegic group had significantly higher risk scores in all four categories, as well as in the total risk score. Although the children with spastic diplegia did not differ significantly from the NH children on the MAI total risk score or any of the categorical risk scores, results of an item analysis reported previously showed that these two groups did differ on seven of the MAI items: posture prone, posture supine, muscle tone summary, trunk rotation, equilibrium responses in prone, summary of automatic reactions, and vocalization.⁴ This suggests that a shorter version of this test should be developed specifically for the early detection of spastic diplegia.

For the children with spastic hemiplegia, significantly higher categorical risk scores were noted in the categories of automatic reactions and volitional movement when compared with children with normal outcomes. These findings imply that the assessment of automatic or postural reactions and volitional movement items, specifically the ability to center the head in the supine position and the ability to bear weight through the shoulders when placed in the prone position,⁴ are important neurodevelopmental attributes that should be examined in infants at risk for hemiplegia.

As Table 5 shows, the infants with quadriplegia scored significantly higher than their normally developing peers on all five risk scores. Many of these chil-

dren had motor problems so obvious at 4 months of age that testing was used primarily to confirm the diagnosis; a detailed description of this group's performance on the MAI individual items has been reported previously.⁴

The final two hypotheses addressed the sensitivity of the Bayley Motor Scale and the MAI in the early detection of the three types of CP. The MAI was clearly superior in identifying more than three times as many children with diplegia at 4 months of age (57.1% vs 15.1%) and more than twice as many children with hemiplegia (63.6% vs 27.3%). The MAI sensitivity for early quadriplegia was about 1.5 times as great as for the Bayley Motor Scale. At 1 year corrected age, however, the Bayley Motor Scale was very sensitive to all three types of CP. Previous research has shown that although the MAI was more sensitive than the Bayley Motor Scale at 4 months of age, it tended to have a lower rate of specificity in that a greater percentage of children with normal outcomes were labeled "at risk."²³

In spite of the very high sensitivity of

the Bayley Motor Scale at 1 year corrected age, it is interesting to note that a definitive diagnosis of CP was not made until much later for the children with spastic hemiplegia (mean age, 21 months). This discrepancy represents caution on the part of our pediatric staff in avoiding unnecessary alarm for the parents.²⁴ In spite of the fact that a diagnosis of CP was not made until after 1 year of age for almost one third of the children with diplegia and hemiplegia, 95% of our children with CP were referred for early intervention services by age 1 year.

CONCLUSIONS

The goal of this study was to retrospectively identify developmental markers that would allow for the detection of three common types of CP during infancy. Assessment tools administered at 4 months' corrected age included the Bayley Mental and Motor Scales and the MAI. While children with quadriplegia differed significantly from low-birth-weight infants with normal developmental outcomes on all parameters of

the Bayley and MAI, neither of these tools had complete success in differentiating children with either spastic diplegia or spastic hemiplegia from their NH peers.

Infants with hemiplegia, however, showed significantly higher MAI risk scores in the categories of automatic reactions and volitional movement and in the total risk score. Both the hemiplegic and diplegic groups showed significantly lower MDIs, with the hemiplegic group also showing a significantly lower PDI when compared with the NH group. The mean developmental indexes were all within normal ranges, however. The total risk score of the MAI was considerably more sensitive in the identification of motor disorder at 4 months of age than was the PDI (Bayley Motor Scale), but the PDI was highly sensitive for all three groups at 12 months' corrected age.

In spite of the fact that the prevalence of CP seems to be increasing among low-birth-weight infants,^{1,25,26} little progress has been made in reliable early diagnosis of this disability. Recently published

retrospective studies have suggested that there are specific early neuromotor behaviors that are predictive of CP,^{4,27} but a definitive assessment tool has yet to be developed that has a high rate of both sensitivity and specificity.

While this study suggests that the MAI is more sensitive than the Bayley

Motor Scale in detecting early signs of CP, the generalizability of these results is limited by the small sample size and the retrospective nature of this study. Further prospective research is needed with larger samples to substantiate these findings. In addition, it would be interesting to study the relative sensi-

tivity and specificity of these standardized neurodevelopmental tests compared with more traditional neurological examinations.

Funding for this study was provided by the Research Trust Fund of the Washington Association for Retarded Citizens, Seattle.

Correction of Atrioventricular Septal Defect

Results Influenced by Down Syndrome?

Thijs W. Vet, Jaap Ottenkamp, MD

• The role of Down syndrome (DS) in the outcome of the surgical correction of atrioventricular septal defect (AVSD) was investigated by the analysis of clinical events among 85 patients. Complete AVSD (cAVSD) was present in 49 patients, of whom 36 (73%) had DS. Thirty patients (83%) survived surgical treatment. Of the 13 patients without DS, 7 (54%) survived. There were four deaths and one late death. Thirty-six patients had partial AVSD (pAVSD), 5 (14%) of whom had DS; all 5 patients are still alive. Thirty (97%) of the 31 patients with pAVSD without DS survived the operation. There were two late deaths. Preoperative selection did not account for the favorable results in children with DS. All early postoperative deaths in cAVSD occurred in children younger than 2 years; low body weight for age seemed to be an important factor in adverse outcome. A large number of patients without DS had other serious congenital malformations. In view of the relatively favorable results in patients with DS, it does not seem warranted to maintain a conservative diagnostic and therapeutic approach of AVSD solely because of concomitant DS.

(AJDC.1989;143:1361-1365)

Atrioventricular septal defect (AVSD), a serious congenital heart malformation, is known to be relatively common in children with Down syndrome (DS). It is estimated that in 40% of children with DS, a congenital heart defect is part of the syndrome and that in 40% of patients with DS and a congenital heart defect, the defect is an AVSD.^{1,2} Furthermore, in DS the complete form of AVSD is more common than the partial form (also known as

"primum type atrial septal defect"), while the reverse is true for the general population.

Recently, several reports have noted that the cardiac malformation in children with AVSD and DS is less complicated than in children with AVSD only. Obstruction of the outflow tract of the left ventricle especially seems to be less frequent and less severe in children with DS.^{3,4} However, Sondheimer et al⁵ reported that the diagnostic and surgical care offered to children with DS and AVSD is often incomplete. Along with other factors, defeatism as to the therapeutic (surgical) possibilities in children with DS can be blamed for this inequality. From a surgical viewpoint, a too conservative diagnostic approach to these children would be unjustified if the relatively optimistic reports^{3,4} on the anatomy of the AVSD in DS were true.

We have asserted our clinical impression that children with DS actually did better after surgical correction of their AVSD than did children without DS. To validate this impression, a comparison of the results of the surgical correction of AVSD in the Leiden clinic (the Netherlands) between children with DS and those without DS was conducted. As DS is not a criterion in the diagnostic process and preoperative selection in our medical center, we are convinced that we can rule out an uneven selection of patients as a source of bias.

PATIENTS AND METHODS

We reviewed the medical records of 85 children consecutively treated for an AVSD by surgical correction in the years 1976 through 1987 in Leiden University Hospital, the Netherlands. The group was divided into the following four subgroups: 36 patients with DS and a complete AVSD (DS-cAVSD), 13 patients without DS with a complete AVSD (NDS-cAVSD), 5 patients with DS

and a partial AVSD (DS-pAVSD), and 31 patients without DS with a partial AVSD (NDS-pAVSD).

For cAVSD and pAVSD separately, we compared the surgical results between patients with and without DS. The diagnosis of DS was based on the typical findings on physical examination and was confirmed by chromosome analysis.

As cAVSD causes much more severe symptoms than pAVSD, and does so at a much earlier age, and as the surgical correction of cAVSD is more complex, it is necessary to make a distinction between the complete and the partial forms. The cAVSD clinically consists of a defect of the atrial and ventricular septum and an unseparated atrioventricular valve that is shared by the left and right sides of the heart. In the pAVSD, the septal defect is limited clinically to the atrial septum, and separate left and right atrioventricular valves are present. The valves, however, are abnormally formed, and, as in the complete form, are malfunctioning.

Attention was given to the postoperative period and to the most recent information available on each patient.

RESULTS

All 85 medical records of our patients were carefully checked for concomitant congenital defects apart from DS and AVSD. Table 1 shows all the anomalies diagnosed before surgery, during surgery, or at postmortem examination. Certain cardiac and noncardiac malformations had already been treated surgically before correction of the AVSD.

Age and weight at operation for each of the patients in the four subgroups are given in Table 2. In Table 3, the same variables are shown for patients with cAVSD treated before their second birthday.

The surgical procedure was the same throughout the entire study period. In cases of cAVSD, separate patches were

used for repair of the atrial and ventricular septum, while the adjacent atrioventricular valve leaves were "sandwiched" between these patches (double-patch sandwich technique). In pAVSD, the interatrial defect was closed by one patch. In cAVSD and pAVSD, modifi-

cations to the atrioventricular valves were tailored to each individual situation, aimed at obtaining optimal valve function.

Mortality in the hospital (number of deaths occurring within 30 days after surgery) for cAVSD was high. Six (17%)

of 36 patients with DS-cAVSD and 6 (46%) of 13 patients in the NDS-cAVSD group died (difference not significant, $P = .08$, χ^2 test)—a total of 12 deaths (24%) in 49 patients (Table 4).

All the patients who died were younger than 2 years. When only the 34 patients with cAVSD who were operated on before their second birthday are considered, mortality in the hospital was 6 (23%) of 26 for patients with DS-cAVSD and 6 (75%) of 8 for patients with NDS-cAVSD (difference is significant, $P = .02$, χ^2 test).

One of the 36 patients with pAVSD who did not have DS died. In the hospital, mortality was 0% for the DS-pAVSD group, 3% for the patients with NDS-pAVSD (difference not significant, $P = .68$, χ^2 test), and 3% for the complete pAVSD group (Table 4).

A second surgical procedure was necessary in 19 patients—6 in the DS-cAVSD group, 2 in the NDS-cAVSD group, and 11 in the NDS-pAVSD group. In most cases, this operation consisted of a second attempt at repair of the "mitral" valve or implantation of a valve prosthesis in this position. One patient with NDS-cAVSD died during the second surgical procedure.

Of the 19 patients who underwent repeated surgery, 5 had a third procedure (1 with DS-cAVSD, 1 with NDS-cAVSD, and 3 with NDS-pAVSD); all 5 patients underwent implantation or replacement of a mitral valve prosthesis. At this third operation, one patient with NDS-pAVSD died.

There were three late deaths in the DS-cAVSD group (all caused by infectious diseases). In the NDS-cAVSD group, the infant who died at reoperation for mitral valve replacement was the only instance of a late death. No late deaths occurred in the DS-pAVSD group, while two late deaths were noted in the NDS-pAVSD group (one after a second reoperation for mitral valve replacement, and one while awaiting such a procedure).

Survival at the time of this study, therefore, was 27 (75%) of 36 patients with DS-cAVSD, 6 (46%) of 13 patients with NDS-cAVSD (difference not significant, $P = .12$, χ^2 test), 5 (100%) of 5 patients with DS-pAVSD, and 28 (90%) of 31 patients with NDS-pAVSD (difference not significant, $P = .47$, χ^2 test).

The follow-up period for these survivors varied from 1 to 130 months, with a mean of 41 months (Table 5).

COMMENT

The uneven distribution of the 85 patients in this study among the four subgroups clearly mirrors the difference in the natural occurrence of cAVSD and pAVSD in children with and without DS. This does not facilitate a comparison in which DS is the variable factor.

Three results, to us, were striking. First, there was a low mortality in the hospital for pAVSD (1 [3%] of 36 patients). Because this figure is so low and because the number of patients with DS-pAVSD both absolutely and relatively was small, a comparison for pAVSD between children with and without DS was impossible.

Second, we found an abundance of congenital malformations besides DS and AVSD in this patient group. It would seem that AVSD, as a rule, is part of a complex of congenital anomalies, both cardiac and noncardiac. An AVSD is generally known as the typical congenital heart defect of DS. As the results of our study show, DS is the single most frequent syndrome in children with AVSD. However, a large proportion of children without DS in this study had other serious congenital anomalies; in a number of cases these anomalies represented recognizable syndromes. To our knowledge, this phenomenon has not been reported previously. We are aware that a retrospective study of surgical results will not generate sufficient data on the natural occurrence of concomitant malformations in AVSD. The frequency of concomitant malformations in this study is high, but because of the uniqueness of each of these anomalies in this study group, their contribution to mortality in the hospital could not be established.

Third, mortality of patients with DS-cAVSD (17%) and patients with NDS-cAVSD (46%) in the hospital greatly differ, as do their long-term survival rates (75% and 46%, respectively).

We also found that all deaths occurred in children younger than 2 years. All children with cAVSD are usually operated on before that age to prevent irreversible pulmonary hypertension. This policy has also been adopted in our cen-

*DS-cAVSD indicates patients with Down syndrome and a complete atrioventricular septal defect; NDS-cAVSD, patients without Down syndrome and a complete atrioventricular septal defect; DS-pAVSD, patients with Down syndrome with a partial atrioventricular septal defect; and NDS-pAVSD, patients without Down syndrome with a partial atrioventricular septal defect.

and patients with NDS-cAVSD operated on before their second birthday (23% and 75%, respectively) is significant ($P = .02$). In this age group, there was a tendency for lower body weights in children without DS. Mean body weight at the time of operation for children younger than 2 years with DS was 6.3 kg, while children without DS at that time had a mean body weight of 4.8 kg (Table 3).

We do not consider the low body weight for age in itself to be the cause of high mortality in the hospital, and thus the explanation for the unfavorable results in patients without DS. More probably, failure to thrive and the high mortality rate share common causative factors.

One of these factors could well be the more severe and often complicated malformation of the heart with AVSD in children without DS.^{3,4} Of the 13 patients with NDS-cAVSD, 3 had a hypoplastic left ventricle, a coarctation of the aorta, or both (patients 57, 62, and 63). All 3 patients were operated on before the age of 2 years and all 3 died. On the contrary, of the 36 patients with DS-cAVSD, only 1 had a hypoplastic left ventricle (patient 25), and 1 other patient had a coarctation of the aorta (patient 1). Both were operated on before their second birthday; the patient with the hypoplastic left ventricle died. Clearly, obstruction of the left ventricle and of its outflow caused an increased surgical risk, notably influencing mortality in the hospital. It is likely that, through failure of the left side of the heart, also due to a larger left-to-right shunt, a more significant failure to thrive may occur.

A hypoplastic left ventricle is a contraindication for correction of cAVSD. Unfortunately, especially the milder forms of right ventricular dominance are difficult to diagnose before surgery.

The factors that might explain the large difference in mortality in the hospital between children with and without DS certainly deserve further research in a prospective study design. We are convinced that a referral or selection bias does not play a role in the advantageous results in children with DS. It is not common practice in any hospital in our region to deny surgery to patients with DS. Furthermore, this study

group included many patients without DS with other serious congenital malformations; if there would have been a referral bias, they also would have suffered from it. According to some, a mild hypothyroidism protects the myocardium of patients with DS during heart surgery. We do not expect that this influence is important. In our experience, the postoperative management of children with DS certainly is not easier. They often require longer periods of postoperative intensive care.

We direct future research toward an explanation for the failure of patients with cAVSD without DS to thrive. Often the clinical condition of these children deteriorates under maximum conservative therapy, and one is forced to attempt surgical repair of the cAVSD, which is a high-risk operation, at a very young age.

We cannot set general rules as to the indication for surgical correction of AVSD in multihandicapped children based on our data, nor do we want to.

From a purely surgical viewpoint, chances for children with AVSD and DS are good, even better than average. In determining individual therapeutic policy, yet other considerations might have to be considered. However, it seems unwarranted to state that DS in general seriously complicates surgical correction of an AVSD.

Koos Zwinderman, PhD, provided us with statistical advice.

Vaginal Opening Measurement in Prepubertal Girls

Christopher W. Goff, MD; Kenneth R. Burke, MD; Christina Rickenback, RN, CPNP; Donald P. Buebendorf, MD

• Normative, age-indexed data regarding the size of the vaginal opening in prepubertal girls have not been previously reported, to our knowledge. Measurement of the apparent transverse diameter of the vaginal opening was done in 273 prepubertal girls as part of their routine health assessment. Vaginal opening diameter tended to enlarge with age and to be larger in the supine knee-chest position than in the supine frog-leg position. An opening greater than 4 mm was distinctly rare. (AJDC. 1989;143:1366-1368)

A vaginal opening with a transverse diameter of greater than 4 mm in a prepubertal girl has been said to be abnormal¹⁻³ and strongly correlated with a history of sexual abuse.^{1,2,4} This claim has profound implications, both legal and medical. Unfortunately, although gynecology texts state that the maximum normal transverse diameter of the vaginal opening, also referred to as the (horizontal) diameter of the hymenal orifice⁵ or vaginal introital diameter,⁴ is 4 to 7 mm in prepubertal girls,^{5,6} not only are supporting studies not cited, but nearly 55% of physicians are either unaware of, or disagree with, the veracity of the textbooks' claims.⁷ A review of the literature verifies that normative data about female genitalia, particularly regarding the transverse diameter of the vaginal opening, are sadly lacking.

Cantwell,² in the follow-up to her original study of 247 prepubertal girls evaluated in a unit designed for children who had been sexually or physically abused or neglected, which reported that 74% of those patients with a transverse vaginal diameter of greater than 4 mm had a history of sexual abuse, noted that only 6 (4%) of 158 girls in that unit who denied having been sexually abused had a transverse diameter of the vaginal opening greater than 4 mm.

In a study of 242 girls between the ages of 1 and 12 years, 144 of whom had a history of sexual abuse or gonococcal infection, White et al⁴ found that 5% of the 75 girls without such a history, but considered "at risk," had a vaginal opening with a transverse diameter greater than 4 mm. None of the 23 girls in the control group had a measurement greater than 4 mm.

As part of a larger study, Emans et al⁸ described a group of 34 girls between the ages of 3 and 6 years, with neither genital complaints nor a history of sexual abuse, who had a mean (\pm SD) vaginal opening of 2.9 ± 1.3 mm (range, 1 to 6 mm). This closely corresponded to the overall control group of 127 girls aged 1 to 14 years in whom the vaginal opening averaged 2.8 ± 1.5 mm. These investigators also reported that the vaginal opening tended to enlarge with age, although complete, age-indexed data were not presented.

Cantwell¹ has pointed out that "accurate measurement (of the vaginal opening) presents problems since the vagina is an elastic organ and the anteroposterior diameter is difficult to measure." Herman-Giddens and Frothingham⁹ have noted that since the moist folds of the hymen may stick together, simple inspection is not adequate to view the vaginal opening. Rather, several seconds of lateral and slight posterior traction are usually required for the hymenal folds to fall apart, allowing visualization of the vaginal opening. Both tension and time of traction might therefore be expected to affect the apparent opening size. Although several authors⁸⁻¹⁰ have stated that there is a significant difference in transverse diameter of the vaginal opening depending on the position (eg, supine frog-leg [SFL], supine knee-chest [SKC], prone knee-chest) that the child is in during measurement, to our knowledge this has not been systematically studied. In view of these issues, it should be understood that the term *vaginal opening* in this report refers specifically to the apparent transverse diameter of the vaginal

opening.

All of the published studies focus primarily on populations of girls who have either a history of being sexually abused or factors that make that diagnosis more likely. Furthermore, they have reported measurements without apparent regard to position during examination, standardization of technique, or age. The control groups described are few in number and may not be representative of the population seen in an average private practice. Therefore, Herman-Giddens and Frothingham⁹ concluded that "normative data on [vaginal opening in] nonabused prepubertal girls needs to be gathered . . . Whether the opening in the hymen slowly increases in diameter . . . is not absolutely known because there are no . . . studies . . ." Our study was designed to provide clinical data on the apparent transverse diameter of the vaginal opening in the SFL and SKC positions in prepubertal girls seen in a private pediatric practice setting using standardized techniques applicable to that setting.

METHODS

As part of routine health maintenance examinations, girls in our pediatric practice have their genitalia inspected. During this examination, in addition to careful inspection of the vulva, labia, clitoris, perineal area, and hymen, the transverse diameter of the

Distribution of vaginal opening measurements in supine frog-leg (SFL) and supine knee-chest (SKC) positions.

Accepted for publication March 25, 1989.

vaginal opening is noted.

To make the procedure nonthreatening, the child is told that "her bottom needs to be checked," and that checking involves both gentle touching and using a flashlight (otoscope) to see better. The patient is instructed to lie down on her back (if not already there), then directed to "bend your knees and put your heels by your bottom; now let your knees fall apart so you look like a frog." The thumbs or index fingers are placed at the midpoint of the labia majora and gentle traction is applied laterally (moving the labia 1 to 1.5 cm on each side) and slightly (0.5 cm) dorsally.

Approximately 4 seconds are given to allow the vaginal opening to reach its maximum size. This time period was arbitrarily chosen as a standard because of clinical experience that most dilatation takes place within the first 1 to 2 seconds, and that cooperating for longer periods of traction is difficult for some young girls. If the hymenal folds fall apart allowing an opening to be seen, the traction is maintained by using the thumb and index finger of the left hand, while a millimeter rule is placed next to the vaginal opening. The transverse diameter of this opening at the level of the hymen is then noted to the nearest millimeter. This measurement is the same as the horizontal hymenal diameter if hymenal tissue is present.

As we often use an otoscope light to allow better visualization of the area, for convenience we taped the measuring device, a 2-cm section of the plastic rule used to read tuberculin tests, flat on the top of the otoscope head. After the measurement has been taken, the child is asked to put her legs together, flex her hips, and hug her knees to her chest, thus placing her in the SKC position, and the procedure is repeated. The entire standardized procedure is a modification of that illustrated and outlined in detail by Herman-Giddens and Frothingham.³

Measurements were prospectively recorded in all girls younger than 8 years of age having routine physical examinations in our office between June 1, 1988, and October 31, 1988. All examinations were done by one of us. While the study design did not allow multiple examiners to measure each child undergoing a routine physical examination, interobserver reliability was checked by comparing the means and variances of the age-indexed measurements found by the different examiners.

RESULTS

Our population base is primarily white (90% to 95%), with small numbers of black (3% to 5%), Hispanic (<3%), and Asian (<3%) youngsters. The majority of families are middle- and upper-

middle class, although at least 7% are covered by state welfare. Two hundred seventy-three girls were examined as part of a routine health assessment. All girls were prepubertal (ie, had Tanner stage I breast and pubic hair development). All hymenal types were included.

Twelve girls were excluded from further analysis because they presented with genital complaints¹⁰ or had tight labial adhesions preventing adequate examination.² Seven other girls (2.7%) had measurements recorded for only the SFL position. In one of these cases, the child refused examination in the

SKC position. All of these children were less than 20 months old. If girls had more than one routine health assessment during the study period, only the first examination for which complete data were obtained has been included.

Results of the findings are shown in the Figure. The distribution of diameters of the vaginal opening was strikingly skewed toward 0 mm. Median and mode values of the vaginal opening in the SFL position were 0 mm until the eighth year. In the SKC position, these values were 0 mm until the fifth year. No patient had a vaginal opening of greater than 4 mm in the SFL position

(indeed, all but two were 3 mm or less), and only three 7-year-old girls did in the SKC position (all three had a 5-mm vaginal opening). The mean vaginal opening in both the SFL and SKC positions increased with age from 0.17 mm (SFL) and 0.26 mm (SKC) in the first year to 1.23 mm (SFL) and 2.50 mm (SKC) in the eighth year (Table 1).

Comparing the vaginal opening as measured in the SFL and SKC positions showed the measurement in the SKC position to be equal or larger than that in the SFL position, except in one case. The difference in measurements in the two positions (SFL value minus SKC value) varied from -1 mm to 4 mm, with mean differences ranging from 0.09 mm to 1.27 mm. Both the mean and SD increased with age (Table 2).

Forty-six girls were examined on more than one occasion. All were under 20 months of age. The measurements obtained varied by a mean of 0.17 mm (SD, 0.53 mm) for measurements obtained in the SFL position and 0.29 mm (SD, 0.58 mm) in the SKC position. We were unable to demonstrate any significant interobserver differences by comparing age-indexed measurements using the analysis of variance (ANOVA) and multiple Student's *t* tests ($P \geq .20$).

COMMENT

We have presented age-indexed data for apparent transverse diameter of the vaginal opening in prepubertal girls in a small-town pediatric practice in Connecticut. Although generalizing our results to all racial or socioeconomic groups should be done with great care, our findings document the assertion that a vaginal opening greater than 4 mm (over 5 mm in girls 7 years of age or older in the SKC position) is distinct-

ly uncommon, and therefore support those researchers who consider it to be abnormal. The data differ from norms previously published.^{4,6,8,11,12} Since these authors neither presented the data used to establish their conclusions nor described a standard technique used in examination of the children (in fact, in several studies, multiple positions were used for measurement^{1,2,3,18}), any attempt to explain the difference would be purely speculative.

In spite of some authors' claims that a vaginal opening of greater than 4 mm should cause one to suspect sexual abuse, no conclusions from our study can be drawn about the causes of an opening greater than 4 mm. Furthermore, it must be stressed that a vaginal opening of less than or equal to 4 mm neither ensures nor suggests that a child has not been sexually abused. Although many authors have made this point,^{1,3,4,7,8-10,14,15} it needs to be stressed.

When reporting and interpreting vaginal opening measurements, particularly in legal proceedings involving possible sexual abuse, care must be taken to either follow our protocol exactly or to specify the position, timing, and order in which the child was examined. We used SKC and SFL positions that we, as others,^{5,12} find less frightening to the child, and which should not be confused with the *prone* knee-chest position recommended by some authors.^{1,16} Our own anecdotal experience concurs with that of Emans et al⁸ who stated that "because the hymenal ring dilates and gapes in the [prone] knee-chest position, measurements should be done in the supine position."

Contrarily, this experience implies that the prone knee-chest position may be advantageous when more detailed inspection of the vagina is necessary in a

child with vaginal pathologic findings. While all but one of our patients had a vaginal opening in the SKC position that was greater or equal to that in the SFL position, this may have been due to the order in which the examination was performed. This possibility needs to be examined, as well as the possibility that a longer period of traction might have allowed for further relaxation and dilatation of the vaginal opening.

The possibility that the vaginal opening associated with one type of intact hymen might be less than that with another (for example, redundant or "flower-petal" type compared with crescentic) was not studied. Furthermore, it should be noted that a vaginal opening of 0 mm does not mean that a girl had an imperforate hymen. Rather, as we did not attempt to separate the hymenal folds with a cotton swab or other instrument, our data suggest that with this standard inspection/examination technique, in many children the hymenal folds do not fall apart, and in those that do, a vaginal opening of greater than 4 mm is rare.

While our data suggest that the vaginal opening does not vary dramatically between examinations, our sample is small and further longitudinal study is indicated. In spite of the suggestion by some authors that a difference of 1 mm in vaginal opening is too small to be useful clinically,⁸ all of the investigators in our study found it surprisingly easy to make the distinction (even in the 0- to 3-mm range before using the measuring device), and found that patients cooperated for the examination. Therefore, we concur with Cantwell¹ who recommended that evaluation of the vaginal opening be included as an important element in the routine health assessment of prepubertal girls.

Ultrasomic Imaging in the Differential Diagnosis of Diffuse Thyroid Disorders in Children

Sten A. Ivarsson, MD; Ulla-Britt Ericsson, MD; Birgitta Fredriksson, MD; Per H. Persson, MD

• In 22 patients with suspected diffuse goiter, the diagnostic accuracy of ultrasonography was compared with that of aspiration biopsy cytology and thyroid antibody testing. Ultrasonography was abnormal in 100% (10/10) of the patients with autoimmune thyroid disease, only 90% (9/10) of whom were identified with antibody testing. All patients with diffuse colloid goiter had normal echo patterns on ultrasound imaging, whereas 29% (2/7) of them had positive results on antibody testing. Whether these are 'false positives' or represent focal thyroiditis remains unclear. Thus, ultrasound imaging stands out as a valuable diagnostic tool for the differential diagnosis of diffuse thyroid disorders in children.

(AJDC. 1989;143:1369-1372)

In adults, ultrasound imaging of the thyroid is accepted as the most sensitive noninvasive method for visualizing the internal anatomy of the thyroid gland.¹ With ultrasound, the normal thyroid is visualized as a smooth, rather echo-rich pattern of stronger echogenicity than the surrounding muscle tissue. The technique has been used successfully in distinguishing between cystic and solid nodules, between solitary and multiple nodules, and in measuring the size of the thyroid gland.¹⁻⁴ There have been several reports that the echogenicity of the thyroid decreases in patients with acute, subacute, and autoimmune thyroiditis. Pöyhönen and Lenko⁵ found ultrasound imaging to be valuable in the differential diagnosis of diffuse goiter in children, whereas Bachrach et al⁶ did not.

The aim of the present prospective study was to compare the accuracy of high-resolution ultrasound imaging with that of other available methods in the differential diagnosis of diffuse thyroid disorders in children.

PATIENTS AND METHODS

The series comprised 22 children (17 girls and 5 boys) ranging in age from 8 to 16 years, 19 of whom were attending the pediatric clinic because of suspected diffuse goiter. Of the remaining 3 cases, 1 came to light during a prospective study of the prevalence of thyroglobulin autoantibodies (Tgab) among children in the city of Malmö in southern Sweden. Ultrasound imaging was done before treatment, except in 2 patients in whom it was done about 1 year after the start of thyroxine (T₄) treatment.

Thyroid hormone analyses were done in accordance with routine procedures at the clinical laboratory. Total T₄ and total triiodothyronine (T₃) were measured with double-antibody radioimmunoassays.⁷ Thyrotropin was measured with an immunoradiometric assay (TSH RIA 200, Pharmacia, Uppsala, Sweden). Thyroglobulin autoantibodies were detected with a solid-phase immunosorbent radioassay.⁸ Microsomal antibodies were detected by immunofluorescence (Serodia AMC, Fujirebio, Tokyo, Japan). A radionuclide scan with technetium Tc 99m pertechnetate and aspiration biopsy cytology were performed in all cases.

The ultrasound imaging was performed by one of us (P.H.P.) who did not know the results of the other analyses. Ultrasonic examination was performed with a real-time ultrasound sector scanner (DRF 400, Diasonics, Milpitas, Calif) using a 10-MHz transducer. All children were examined while they were in the supine position with the neck extended. The thyroid was always investigated both in the transverse and longitudinal projections. The thyroid volume was expressed in milliliters by measuring the long axis and the transverse and anteroposterior diameters of both thyroid lobes. The size of the isthmus was not included in the calculation as it was found to contribute very little to the total thyroid volume. In cases where the long axis exceeded 30 mm (50%), the lobe had to be measured in two sections, as the transducer aperture was only 30 mm. The procedure used for measuring the long axis was as follows: The caudal limit of the thyroid lobe was located and positioned at the lower margin of the transducer aperture. A central structure was then selected on the long axis of the thyroid and its distance from the caudal limit measured. The transducer was then moved cranially along the long axis to reposition the chosen structure near the lower margin of the aperture, and its distance from the cranial limit of the thyroid

lobe was measured, the sum of the two measurements being taken as the dimension of the long axis. Although not entirely satisfactory, this procedure had to be adopted as no other high-resolution transducer with a wider-image angle was available.

The echo pattern of a normal thyroid gland is characterized by high-amplitude echoes uniformly scattered throughout the gland. The surface area is smooth. Reference values for thyroid gland volume had been established for children from 5 to 17 years of age and presented in a previous report.⁹

RESULTS

Aspiration biopsy cytology was performed in all children. Juvenile autoimmune thyroid disease (AITD) was confirmed in 10 patients, diffuse colloid goiter in 7 patients, and subacute thyroiditis (de Quervain's) in 1 patient. Although aspiration biopsy cytology findings were inconclusive in 4 patients, 1 patient showed changes both of AITD and the de Quervain type of thyroiditis. The diagnoses and results of antibody testings are given in the Table.

On the basis of the clinical and laboratory findings, all but 1 of the 22 children were euthyroid. Thyrotropin values were slightly high in 6 children, 4 of whom had AITD and 2 of whom had inconclusive biopsy findings. In all but 1 of the 10 patients with AITD, a goiter was suspected on palpation. In 8 of the patients, an enlarged gland was found on ultrasound imaging, and in 14 patients, the gland was considered to be enlarged at thyroid scintigraphy.

Ultrasound Findings

All patients with AITD on aspiration biopsy cytology had abnormal echo patterns with hypoechogenicity on the ultrasound image. The echogenicity was not homogeneous, with small areas of normal echoes surrounded by areas with low or very low echogenicity giving a patchy appearance. Essentially as outlined by Yoshida et al,¹⁰ though with minor modifications, the degree of abnormality was graded from 0 to 4 as follows: grade 0, diffuse—high amplitude echo throughout the lobe of the thyroid (normal) (Fig 1); grade 1, sim-

*T₃ indicates triiodothyronine (reference interval, 0.9 to 3.2 nmol/L); T₄, thyroxine (reference interval, 50 to 150 nmol/L); Tgab, thyroglobulin antibody; Mab, microsomal antibody; ⁹⁹Tc, technetium Tc 99m; Neg, negative; N, Normal; C, colloid goiter; AITD, autoimmune thyroid disease; and D, diffuse goiter.
†The reference interval for thyrotropin is 0.4 to 4.0 mU/L.

Fig 1.—Longitudinal section of normal thyroid lobe with uniform echo pattern. The arrowheads mark the border of the thyroid lobe.

Fig 2.—Longitudinal (left) and cross-sectional (right) scans of thyroid gland. Irregular small areas of decreased echogenicity are seen throughout the gland and are classified as grade 3. The arrowheads mark the border of the thyroid lobe and isthmus.

Fig 3.—Cross-sectional scan of a completely abnormal thyroid gland with apparently no normal parenchyma, classified as grade 4. The arrowheads mark the border of the thyroid lobe and isthmus.

Fig 4.—“Pseudocystic” image concomittant with de Quervain's thyroiditis, classified as grade 4. The arrowheads mark the border of the thyroid lobe and isthmus.

ple enlargement of the thyroid gland with a normal echo pattern; grade 2, small areas with low echo amplitude in some part of the gland; grade 3, small areas of hypoechogenicity throughout the whole thyroid surrounded by some normal echoes (Fig 2); and grade 4, completely abnormal echo pattern with large cystic regions and no apparently normal parenchyma (Fig 3).

There was no correlation between the degree of abnormality on the ultrasound imaging and the Tgab titer. All patients with diffuse colloid goiter on aspiration biopsy cytology had normal echo patterns. The gland of the patient with a granulomatous thyroiditis (de Quervain's thyroiditis) differed in echo pattern from those of the patients with AITD by manifesting a patchy echo pattern with pronounced hypoechogenicity giving a "pseudocystic" image unlike that of normal and solid tissue (Fig 4).

Thyroid Antibody Testing

Thyroglobulin autoantibodies were detected in 9 (90%) of 10 patients with AITD. Two patients with colloid goiter were also Tgab positive, as was the patient with subacute thyroiditis. All 4 patients with uncertain diagnoses were also Tgab positive.

Microsomal antibodies were detected in only 4 (40%) of 10 patients with AITD and in none of the patients with diffuse colloid goiter. Three patients had inconclusive diagnoses.

COMMENT

In the present study, all children with AITD showed abnormalities on ultrasound imaging and manifested comparable patterns of nonhomogeneous hypoechogenicity. The echo pattern differed both from the normal echoes found in the children with colloid goiter and from the multimicrocystic appearance in the patient with granulomatous thyroiditis. In agreement with our results, Pöyhönen and Lenko⁵ found abnormal ultrasound imaging in 92% of their children with AITD, whereas thyroid ultrasound imaging in a retrospective study by Bachrach et al⁶ was found to be of limited value in the differential diagnosis of diffuse thyroid lesions, despite that they identified 47% of the patients with Hashimoto thyroiditis. In contrast to the echo pattern observed in all our patients with AITD, Espinasse¹¹ found a homogeneous micro-echo pat-

tern in a patient with chronic lymphocytic thyroiditis. It is believed that the positive findings on ultrasonic imaging were due to a marked infiltration of inflammatory cells and formation of germinal centers, as these are always very echolucent.¹⁰ Therefore, it is possible that the difference in echo patterns between our patients with AITD and those of Espinasse may be due to differences in the degree and pattern of lymphocytic infiltration and in the degree of fibrosis. There is a correlation between the level of the echo amplitude and the degree of lymphocytic infiltration and fibrosis.⁵ Hayashi et al¹² were able to differentiate severe and less severe cases of thyroiditis according to the echogenicity pattern of the thyroid; they reported that every hypoechogenic area of the thyroid was severely degenerated, with disappearance of the thyroid follicles.

Ultrasonic imaging identified all patients with AITD on aspiration biopsy cytology, whereas thyroid antibody testing identified only 90% (9/10). The failure to detect Tgab in 1 of the patients with AITD may have been due to the formation of circulating immune complex giving false-negative antibody test results. Two patients with colloid goiter (29%) were Tgab positive, which is comparable with the report of Ling et al¹³ in which 2 (25%) of 8 of the subjects with colloid goiter were positive for serum antithyroid antibodies. All 4 patients with uncertain diagnoses also had detectable Tgab. These patients may only have had focal thyroiditis without fibrosis and Tgab was not, therefore, detectable either on ultrasonic imaging or with aspiration biopsy cytology. The patient with both AITD and de Quervain's thyroiditis on aspiration biopsy cytology had Tgab, and, thus, AITD is the most probable diagnosis, though further follow-up of this patient will be required to establish which diagnosis is correct.

The other patient with de Quervain's thyroiditis also had myasthenia gravis; in this patient, the clinical picture was not typical of de Quervain's thyroiditis, though both the aspiration biopsy cytology and ultrasound findings were. Future clinical observations may provide a clue to these apparently anomalous findings. In seven patients with autoimmune thyroiditis, an ultrasonic examination was repeated 1½ to 2 years after

the first; in five patients the echo pattern had progressed, and in two patients it was unchanged, but in none of them had it improved or normalized, though during thyroxine treatment the gland had decreased in size and was below the normal range.

In conclusion, our study shows that ultrasonic imaging is a valuable method with good diagnostic accuracy in the differential diagnosis of diffuse thyroid disorders. The examination is noninvasive and easy to perform and is well tolerated by children and acceptable to their parents. There are no difficulties in differentiating between diffuse colloid goiter and thyroiditis. Even without great experience, grading is simple and easily performed. Perhaps an ideal diagnostic strategy in pediatrics might be the combination of ultrasonic imaging with the determination of Tgab.

Kwell® is a registered trademark of Reed & Carnrick. NI-139

NIX[®] FOR LICE[®]

CREME RINSE

permethrin 1%

PEDICULICIDAL/OVICIDAL ACTIVITIES: *In vitro* data indicate that permethrin has pediculicidal and ovicidal activity against *Pediculus humanus var. capitis*. The high cure rate (97-99%) of Nix in patients with head lice demonstrated at 14 days following a single application is attributable to a combination of its pediculicidal and ovicidal activities and its residual persistence on the hair which may also prevent reinfestation.

INDICATIONS AND USAGE: Nix is indicated for the single-application treatment of infestation with *Pediculus humanus var. capitis* (the head louse) and its nits (eggs). Retreatment for recurrences is required in less than 1% of patients since the ovicidal activity may be supplemented by residual persistence in the hair. If live lice are observed after at least seven days following the initial application, a second application can be given.

CONTRAINDICATIONS: Nix is contraindicated in patients with known hypersensitivity to any of its components, to any synthetic pyrethroid or pyrethrin, or to chrysanthemums.

WARNING: If hypersensitivity to Nix occurs, discontinue use.

PRECAUTIONS:

General: Head lice infestation is often accompanied by pruritus, erythema, and edema. Treatment with Nix may temporarily exacerbate these conditions.

Information for Patients: Patients with head lice should be advised that itching, redness, or swelling of the scalp may occur after application of Nix. If irritation persists, they should consult their physician. Nix is not irritating to the eyes; however, patients should be advised to avoid contact with eyes during application and to flush with water immediately if Nix gets in the eyes. In order to prevent accidental ingestion by children, the remaining contents of Nix should be discarded after use.

Combing of nits following treatment with Nix is not necessary for effective treatment. However, patients may do so for cosmetic or other reasons. The nits are easily combed from the hair treated with Nix after drying.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Six carcinogenicity bioassays were evaluated with permethrin, three each in rats and mice. No tumorigenicity was seen in the rat studies. However, species-specific increases in pulmonary adenomas, a common benign tumor of mice of high spontaneous background incidence, were seen in the three mouse studies. In one of these studies there was an increased incidence of pulmonary alveolar-cell carcinomas and benign liver adenomas only in female mice when permethrin was given in their food at a concentration of 5000 ppm. Mutagenicity assays, which give useful correlative data for interpreting results from carcinogenicity bioassays in rodents, were negative. Permethrin showed no evidence of mutagenic potential in a battery of *in vitro* and *in vivo* genetic toxicity studies. Permethrin did not have any adverse effect on reproductive function at a dose of 180 mg/kg/day orally in a three-generation rat study.

Pregnancy: Teratogenic Effects: Pregnancy Category B: Reproduction studies have been performed in mice, rats, and rabbits (200-400 mg/kg/day orally) and have revealed no evidence of impaired fertility or harm to the fetus due to permethrin. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers: It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk and because of the evidence for tumorigenic potential of permethrin in animal studies, consideration should be given to discontinuing nursing temporarily or withholding the drug while the mother is nursing.

Pediatric Use: Nix is safe and effective in children two years of age and older. Safety and effectiveness in children less than two years of age have not been established.

ADVERSE REACTIONS: The most frequent adverse reaction to Nix is pruritus. This is usually a consequence of head lice infestation itself, but may be temporarily aggravated following treatment with Nix. 5.9% of patients in clinical studies experienced mild temporary itching; 3.4% experienced mild transient burning/stinging, tingling, numbness, or scalp discomfort; and 2.1% experienced mild transient erythema, edema, or rash of the scalp.

DOSAGE AND ADMINISTRATION:

Adults and Children: Nix is intended for use after the hair has been washed with shampoo, rinsed with water and towel dried. Apply a sufficient volume of Nix to saturate the hair and scalp (especially behind the ears and on nape of the neck). Nix should remain on the hair for 10 minutes before being rinsed off with water. A single treatment is sufficient to eliminate head lice infestation. Combing of nits is not required for therapeutic efficacy, but may be done for cosmetic reasons or to meet school "no nit" policies. A nit comb is provided.

SHAKE WELL BEFORE USING.

HOW SUPPLIED: Nix (Permethrin) 1% (wt./wt.) Creme Rinse is supplied in plastic squeeze bottles that contain 2 fl. oz. weighing 56 g. (NDC-0081-0780-81)

Store at 15°-25°C (59°-77°F).

Chair, Department of Pediatrics

The Allentown Hospital — Lehigh Valley Hospital Center, an 823-bed tertiary care teaching hospital in eastern Pennsylvania, is seeking a board certified pediatrician to become the first full-time Chair of its Department of Pediatrics. The successful candidate will be an accomplished clinician with the enthusiasm and vision to build a progressive, well-organized department. We will look to the Chair to create programs to assist us in providing better inpatient services, to recruit subspecialists appropriate to a service area of close to ¾ of a million people and to encourage links with educational institutions aimed at the possible development of a relationship with a tertiary pediatric program.

Our hospital is a component of HealthEast, Inc., a 1,031-bed system. Its Pediatrics Department includes a 28-bed Pediatric Unit and a 20-bed Level III Regional Neonatal Intensive Care Unit. There are 38 pediatricians on the staff of the hospital, 11 of whom are subspecialists. The pediatricians care for over 3,000 newborns each year.

Located in a prosperous and desirable area of Pennsylvania, Allentown is one hour from Philadelphia, one and one-half hours from New York City and close to the beautiful Pocono Mountains.

Interested candidates should submit their curriculum vitae in confidence to: **Martha A. Lusser, M.D., Chair, Search Committee, c/o HealthSearch, 50 College Drive, Allentown, PA 18104 or call (215) 778-7993 for descriptive brochure.**

Now, your review and update for board exams and practice

Sponsored by the Osler Institute

OBJECTIVES:

- Improve basic and clinical knowledge in pediatrics
- Assist residents and fellows in organizing study
- Prepare candidates to take examinations
- Provide practicing pediatricians with a review and update

METHODS:

- HOME STUDY MATERIALS consisting of a syllabus of questions with assignments and answers
- SEMINAR with projection slides and syllabus
- PRACTICE EXAMS with multiple choice questions

The faculty was outstanding. The most pleasant thing was learning a tremendous amount, not only from world-famous authorities but from people who are relatively unknown as well."

"Accommodations were comfortable..."

GOALS AND LOCATION: The course is held four months before and the week before board exams. Sites are chosen for excellent study and minimal cost of hotel and travel for board candidates. Home study questions will be sent before the course. Your best value is to repeat the seminar for half price the week before boards exams. Topics and faculty are upgraded for each program. Our hotel rates are typically \$66 to \$80 single and \$80 to \$98 double. Please wait for instructions before buying travel tickets.

"...and those little extras..."

LOWEST AIR FARES: Reliable Travel offers you the lowest air fare — often below super-saver rates. Please call toll-free 1-800-548-8185 and identify yourself with this Osler course for special group fares.

"...remarkably complete and pleasant..."

PLACEMENT SERVICE: For a practice opportunity write or call 1-800-356-7537.

"...the most education for the money..."

FEES AND COURSE HOURS:

- Course Hours: 60 hrs.
- Practicing Pediatrician: \$690
- Residents and Fellows: \$460
- Repeating course within 3 yrs.: half price
- Add 10% within 10 days of course.
- Fees do not include lodging or meals.
- Attendees not in course hotel add \$11/day.
- Deposit of \$50 will reserve your position.
- Most home-study material will be mailed after half the registration fee is received.

"...home study material was extremely helpful..."

REFUNDS: Subject to a \$50 fee, refunds will be made until the seminar begins.

- Cancellation after mailing home study material requires retention of half the fee.

"I feel [the course] helped me pass the boards..."

They trust you to recommend what's best for them.

LIQUIPRIN has earned the confidence of parents and pediatricians with dependable relief of fever and pain for over 25 years.

The LIQUIPRIN acetaminophen formula does not contain aspirin or alcohol and has a pleasant-tasting fruit flavor that babies like.

The LIQUIPRIN advanced dropper system has a larger tube and bulb, making each dose easier to measure. The bottle is unbreakable plastic with a safety-sealed, child-proof cap. And LIQUIPRIN is priced well below Tylenol.[®]

LIQUIPRIN. Pediatricians recommend it over 1½ million times a year. For good reason.

Available as an Elixir, too.

RICHARD W. GAST
PRESIDENT

... on the consumer promotion of infant formula.

There is a development that undermines your control over the infant's diet and health, and that undermines breastfeeding—the advertisement of formulas directly to the mother through TV, magazines and mail.

On June 1, the President of the American Academy of Pediatrics sent a letter to all Fellows of the Academy reaffirming its stance against consumer advertising, and expressing concern that other formula companies might follow Nestlé/Carnation.

This concern was justified. On June 15, it was announced at a press conference that Mead Johnson/Bristol-Myers will be producing an infant formula to be sold and marketed under the Gerber label. Part of the program is a multimillion-dollar budget for advertising the formula directly to mothers via TV and print.

Speaking at the press conference, Gerber Products Division President Robert L. Johnston, Jr., said that Gerber was entering the market because it had, "identified significant changes in usage that convinced us the timing was right...."

"First," he said, "there is a rapid decline in breast-feeding after mothers leave the hospital." And, "... parent decision regarding baby formula brand selection has grown...."

The irony is inescapable and appalling. In other words, because breastfeeding is declining, more infant formulas should be promoted to the mother. In other words, because some mothers are making feeding decisions on their own, even more mothers should follow suit.

When Nestlé/Carnation entered the marketplace and, again, when Mead Johnson/Bristol-Myers joined with Gerber, we reexamined the Ross philosophy of promoting SIMILAC® Infant Formulas. The result of our deliberations was an even deeper resolve to support the doctor/patient relationship.

Our philosophy remains unchanged. Ross Laboratories has no plans to resort to direct consumer advertising for SIMILAC and our other infant formula products.

We will continue as an ally of health care professionals by supporting your prerogative to prescribe and recommend products as training and experience dictate.

We stand behind you.

Richard W. Gast

Advertising Principles: Each advertisement in this issue has been reviewed and complies with the principles governing advertising in AMA scientific publications. A copy of these principles is available on request. The appearance of advertising in AMA publications is not an AMA guarantee or endorsement of the product or the claims made for the product by the manufacturer.

NEW MANUSCRIPT PROCEDURE

On January 1, 1988, *AJDC* initiated a new procedure. Manuscripts submitted to *AJDC* will NO LONGER BE RETURNED, except in the case of accepted manuscripts or those undergoing author revision. Original artwork and photographs will be returned.

General Information.—Please send manuscripts and correspondence by first-class mail (do not use registered, certified, or express mail) to the Editor, Vincent A. Fulginiti, MD, *AJDC*, Dean's Office, Room 1529, Tulane University, School of Medicine, 1430 Tulane Avenue, New Orleans, LA 70112. All accepted manuscripts are subject to copy editing. The corresponding author will receive an edited typescript and layout for approval. Forms for ordering reprints are included with the edited typescript. Reprints are shipped six to eight weeks after publication. Proofs will be sent for approval if requested by the author and if printing deadlines permit. The author is responsible for all statements in his/her work, including changes made by the copy editor.

Conforming with all of the steps listed below will facilitate the editorial processing of your manuscript.

Step 1.—Cover Letter.—All manuscripts must be accompanied on submission by a cover letter giving the name, address, affiliation, and telephone number of the corresponding author. The letter must include ALL of the following statements SIGNED BY ALL AUTHORS (ORIGINAL SIGNATURES):

1. **Copyright Release.**—“In consideration of the American Medical Association's taking action in reviewing and editing this submission, the author(s) undersigned hereby transfer(s), assign(s), or otherwise convey(s) all copyright ownership to the AMA in the event that this work is published by the AMA.”

2. **Statement of Affirmation.**—“This manuscript has not been published anywhere in any language and is not under simultaneous consideration by another publication. This manuscript is original and ALL authors have seen and approve of its contents.”

3. **Financial Disclosure.**—List all affiliations with or financial involvement in organizations or entities with a direct financial interest in the subject matter or material of the research discussed in the manuscript (eg, employment consultancies, stock ownership) OR include a statement disclaiming any such involvement. All such information will be held in confidence during the review process. Should the manuscript be accepted, the Editor will discuss with the author the extent of disclosures appropriate for publication. All accepted manuscripts become the permanent property of the publisher (AMA) and may not be published elsewhere without written permission from the AMA. After publication certain articles may appear in translation in the foreign-language edition(s) of *AJDC*.

Step 2.—Manuscript Format.—All articles submitted should have the following features:

1. Four copies of the manuscript should be submitted; three are for transmission to referees and one is to be retained in the editorial office. We prefer an original and three copies.

2. Manuscripts should be typed in triple-spaced format on heavy-duty white bond paper, 21.6×27.9 cm (8½×11 in) with 2.5-cm (1-in) margins. Do not use justified right margins.

3. Title should be no more than 75 characters.

4. Authors should be limited to six, all of whom have contributed to the study and manuscript preparation, are familiar with its substance, and are able to defend its conclusions.

5. The title page should give full names, degrees, and academic affiliations of all authors, address for request of reprints, and, if the manuscript was presented at a meeting, the organization, place, and exact date on which it was read.

6. Writing style should conform to proper English usage and syntax; consult the *American Medical Association Manual of Style*, available from Williams & Wilkins, 428 E Preston St, Baltimore, MD 21202.

7. Abstract should be limited to 135 words or less.

8. Each table should be typed, with a title, on a separate sheet of paper, with each line, including headings, double-spaced. Continuations should be on a second sheet with all headings repeated.

9. Use Système International (SI) measurements throughout the manuscript.

10. Illustrations should be high-contrast, glossy prints, in quadruplicate, unmounted and untrimmed; lettering should be legible after reduction to column size. Figure number, name of first author, and arrow indicating “top” should be typed on a gummed label and affixed on the back of each illustration. Do not write directly on the print.

Magnification and stain should be provided for histologic sections. Full-color illustrations should be submitted as 35-mm, positive color transparencies, mounted in cardboard and carefully packaged. Do not submit glass-

fee must accompany submission.

All photographs in which there is a possibility of patient identification should be accompanied by a signed statement of consent from both parents (or guardians). Covering eyes to mask identity is not sufficient.

11. References should be listed in order of their appearance in the text, type double-spaced, and in AMA format. Please follow the exact order of information and punctuation in the examples below. Note: List all authors and/or editors up to six; if more than six, list the first three and “et al.”

Journal articles: Scott GB, Buck BE, Leterman JG, Bloom FL, Parks WP. Acquired immunodeficiency syndrome in infants. *N Engl J Med*. 1984;310:76-81.

Books: Naeye RL. How and when does antenatal hypoxia damage fetal brains? In: Kubli F, Patel N, Schmidt W, Linderkamp O, eds. *Perinatal Events and Brain Damage in Surviving Children*. New York, NY: Springer Verlag NY Inc; 1988:83-91.

Unpublished data, personal communications, or manuscripts “in preparation” or “submitted” should not be included in the list of references. Such material, if essential, may be incorporated in the body of the article.

Authors are responsible for the accuracy of the references.

12. Investigations involving human subjects require a specific statement in the “Methods” section that an appropriate institutional review board approved the project and/or that informed consent was obtained from both legal guardians and/or child, if appropriate.

13. Illustrations and tables from other publications should be suitably acknowledged, with written permission from publisher and author. Brief acknowledgements to specific contributors directly involved in the content of the manuscript may be placed at the end of the text, before the references. General acknowledgements will be deleted.

Step 3.—Special Departments.—Criteria for several special departments are given below.

1. *The Pediatric Forum.*—This is the place for comment, criticism, observations, and discussion of “issues of current concern and importance for children's health,” in addition to letters that comment on articles in previous issues of *AJDC*. The Editor reserves the right to conduct review of and to edit all submissions. THE READER SHOULD SUBMIT TRIPLE-SPACED COPY CLEARLY MARKED “FOR PUBLICATION” AND SIGNED BY ALL AUTHORS. REFERENCES, IF INCLUDED, SHOULD CONFORM TO THE USUAL AMA FORMAT. Copyright assignment, signed by all authors, must accompany the original submission.

2. *From Research to Relevance.*—PURPOSE: To focus on significant research that has a high probability of being translated into clinical usefulness.

3. *Educational Interventions.*—PURPOSE: To share information concerning any educational efforts in the broad field of pediatrics.

4. *Sports Medicine.*—PURPOSE: To provide current information related to the medical needs of young athletes, as pertinent to counseling young athletes and their parents regarding sports participation and practices contributing to the health maintenance of the athlete, as well as current concepts in the prevention, diagnosis, and treatment of sports-related illnesses and injuries.

5. *Picture of the Month.*—Submissions should be sent directly to Murray Feingold, MD, National Birth Defects Center, Kennedy Memorial Hospital, 30 Warren St, Brighton, MA 02135, and should conform to the format for original articles in terms of the text, references, and illustrations.

6. *Radiological Case of the Month.*—Submissions should be sent directly to Beverly P. Wood, MD, University of Rochester Medical Center, 601 Elmwood Ave, PO Box 648, Rochester, NY 14642. Submissions should conform to the format for original articles in terms of the text, references, and illustrations.

Sometimes you need a steroid...

When inflammation and erythema complicate diaper candidiasis, you may want the fast anti-inflammatory and antipruritic relief of a topical steroid in addition to an effective antifungal. Mycolog[®]-II combines nystatin, a proven antifungal for candidiasis, with triamcinolone acetonide, a medium-potency steroid—so that baby can get prompt relief with the first application. And it's been proven effective for use in children as young as 2 months.^{1*}

MYCOLOG[®]-II (nystatin and triamcinolone acetonide cream, USP) **D.A.W.[†]**

Prompt relief for the symptoms of diaper candidiasis.

Sometimes you don't.

Mycostatin® is the only topical powder that contains a proven antifungal, nystatin. This helps keep baby dry and comfortable as it clears the candidiasis. Mycostatin Powder contains no preservatives and is well tolerated by children of all ages.

Reference: 1. Mycolog-II full prescribing information.

*Pediatric patients may demonstrate greater susceptibility to topical corticosteroid-induced HPA (hypothalamic-pituitary-adrenal) axis suppression and Cushing's syndrome than mature patients because of a larger ratio of skin surface area to body weight.

†Protect your choice—specify "Dispense as Written" or as your state requires.

MYCOSTATIN®

(nystatin topical powder, USP)

The comfort of powder, the efficacy of nystatin.

Innovation in topical delivery

Nystatin and triamcinolone acetonide
Cream/Ointment

For Dermatologic Use Only
Not for Ophthalmic Use

INDICATIONS AND USAGE: These preparations are indicated for the treatment of cutaneous candidiasis; it has been demonstrated that the nystatin-steroid combination provides greater benefit than the nystatin component alone during the first few days of treatment.

CONTRAINDICATIONS: These preparations are contraindicated in those patients with a history of hypersensitivity to any of its components.

PRECAUTIONS: General—Systemic absorption of topical corticosteroids has produced reversible hypothalamic-pituitary-adrenal (HPA) axis suppression, manifestations of Cushing's syndrome, hyperglycemia, and glucosuria in some patients.

Conditions that augment systemic absorption include application of the more potent steroids, use over large surface areas, prolonged use, and the addition of occlusive dressings.

Therefore, patients receiving a large dose of any potent topical steroid applied to a large surface area should be evaluated periodically for evidence of HPA axis suppression by using the urinary free cortisol and ACTH stimulation tests, and for impairment of thermal homeostasis. If HPA axis suppression or elevation of the body temperature occurs, an attempt should be made to withdraw the drug, to reduce the frequency of application, or to substitute a less potent steroid.

Recovery of HPA axis function and thermal homeostasis are generally prompt and complete upon discontinuation of the drug. Infrequently, signs and symptoms of steroid withdrawal may occur, requiring supplemental systemic corticosteroids.

Children may absorb proportionally larger amounts of topical corticosteroids and thus be more susceptible to systemic toxicity (see PRECAUTIONS, Pediatric Use).

If irritation or hypersensitivity develops with the combination nystatin and triamcinolone acetonide, treatment should be discontinued and appropriate therapy instituted.

The treated skin area should not be bandaged or otherwise covered or wrapped as to be occluded.

Laboratory Tests—If there is a lack of therapeutic response, appropriate microbiological studies (e.g., KOH smears and/or cultures) should be repeated to confirm the diagnosis and rule out other pathogens, before instituting another course of therapy.

A urinary free cortisol test and ACTH stimulation test may be helpful in evaluating hypothalamic-pituitary-adrenal (HPA) axis suppression due to corticosteroid.

Carcinogenesis, Mutagenesis, and Impairment of Fertility—Long-term animal studies have not been performed to evaluate carcinogenic or mutagenic potential, or possible impairment of fertility in males or females.

Pregnancy Category C—There are no teratogenic studies with combined nystatin and triamcinolone acetonide. Corticosteroids are generally teratogenic in laboratory animals when administered systemically at relatively low dosage levels. The more potent corticosteroids have been shown to be teratogenic after dermal application in laboratory animals. Therefore, any topical corticosteroid preparation should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Topical preparations containing corticosteroids should not be used extensively on pregnant patients, in large amounts, or for prolonged periods of time.

Nursing Mothers—It is not known whether any component of this preparation is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised during use of this preparation by a nursing woman.

cream formulation on a limited number of pediatric patients ranging in age from two months through 12 years, the combination cleared or significantly ameliorated the disease state in most patients.

Pediatric patients may demonstrate greater susceptibility to topical corticosteroid-induced hypothalamic-pituitary-adrenal (HPA) axis suppression and Cushing's syndrome than mature patients because of a larger skin surface area to body weight ratio.

HPA axis suppression, Cushing's syndrome, and intracranial hypertension have been reported in children receiving topical corticosteroids. Manifestations of adrenal suppression in children include linear growth retardation, delayed weight gain, low plasma cortisol levels, and absence of response to ACTH stimulation. Manifestations of intracranial hypertension include bulging fontanelles, headaches, and bilateral papilledema.

Administration of topical corticosteroids to children should be limited to the least amount compatible with an effective therapeutic regimen. Chronic corticosteroid therapy may interfere with the growth and development of children.

Parents of pediatric patients should be advised not to use tight-fitting diapers or plastic pants on a child being treated in the diaper area, as these garments may constitute occlusive dressings.

ADVERSE REACTIONS: Acneiform eruption has been reported to occur in approximately one percent of patients with use of combined nystatin and triamcinolone acetonide.

Nystatin is virtually nontoxic and nonsensitizing and is well tolerated by all age groups, even during prolonged use. Rarely, irritation may occur.

The following local adverse reactions are reported infrequently with topical corticosteroids (reactions are listed in an approximate decreasing order of occurrence): burning, itching, irritation, dryness, folliculitis, hypertrichosis, acneiform eruptions, hypopigmentation, perioral dermatitis, allergic contact dermatitis, maceration of the skin, secondary infection, skin atrophy, striae, and miliaria.

Patients should report any signs of local adverse reactions.

OVERDOSAGE: Topically applied corticosteroids can be absorbed in sufficient amounts to produce systemic effects (see PRECAUTIONS, General); however, acute overdosage and serious adverse effects with dermatologic use are unlikely.

J4-019B/J4-110

MYCOSTATIN® CREAM

Nystatin Cream USP

MYCOSTATIN® TOPICAL POWDER

Nystatin Topical Powder USP

MYCOSTATIN® OINTMENT

Nystatin Ointment USP

INDICATIONS AND USAGE

Mycostatin (nystatin) topical preparations are indicated in the treatment of cutaneous or mucocutaneous mycotic infections caused by *Candida* (*Monilia*) *albicans* and other *Candida* species.

CONTRAINDICATIONS

Mycostatin topical preparations are contraindicated in patients with a history of hypersensitivity to any of their components.

PRECAUTIONS

Should a reaction of hypersensitivity occur the drug should be immediately withdrawn and appropriate measures taken.

These preparations are not for ophthalmic use.

ADVERSE REACTIONS

Nystatin is virtually nontoxic and nonsensitizing and is well tolerated by all age groups including debilitated infants, even on prolonged administration. If irritation on topical application should occur, discontinue medication.

The Pediatric Forum

This department of AJDC is reserved for comment, criticism, observation, and discussion of "issues of current concern and importance for children's health." The Editor encourages our readers to express themselves on a variety of topics and issues. Further, we encourage the submission of unique and brief clinical and scientific observations that do not fulfill the criteria for original articles.

A 1-Month Elective in International Health for Senior Pediatric Residents

Sir.—During the past 10 years the number of inquiries concerning the availability of electives in international health from applicants to the pediatric program at the University of Arizona, Tucson, has been steadily increasing. A review of the personal statements of resident applications for 1989-1990 revealed that 20% (18/91) of the candidates had already had experience in international health, another 7% (7/91) will have had international health experience by the time they start their residency, and 3% (3/91) expressed an interest in international health work. This represents a total of 31% (28/91) of this year's applicants. This may, of course, be a biased sample since resident interest in international health may preferentially apply to our program. At least 10% of each class of graduating medical students at our institution have had international health experience. This has prompted the creation of an elective in international health to provide senior pediatric residents the opportunity to validate the depth of their interest. The purpose of this report is to outline how this elective program was implemented, describe its curriculum, and relate 3 years of experience with it.

Implementation.—There are two major obstacles in starting an elective in international health. One relates to establishing contact with a pediatric department in another country and being assured that the experience will be worthwhile. In our department, this was overcome by an association one of our faculty members (B.D.) had maintained with Project HOPE. Through that contact, the pediatric department of the teaching hospital in Tegucigalpa, Honduras, was identified as a possible location for a 1-month elective program for our residents who were fluent in Spanish. Project HOPE had a program in Honduras, and its director was very cooperative in assisting with the development of the program. A visit was made to the proposed site by one of us (B.D.) to

give some lectures, to work with the faculty and house staff, and to ascertain the feasibility of establishing an elective there.

The faculty in Tegucigalpa is well trained. There are more than 200 pediatric beds for infants and children who have an array of common and not-so-common diseases. There is a separate large ward for patients with meningitis, an orthopedic unit for those with acute and chronic osteomyelitis, a rheumatic fever ward, an oral rehydration unit, a large ward for children with pneumonia, a newly opened oncology/hematology ward filled with children with lymphomas and retinoblastomas in various stages and an occasional child with histiocytosis X, and a large malnutrition unit for infants and children with marasmus and kwashiorkor. In addition, there are many children with the tropical diseases endemic to this Central American country, such as cutaneous leishmaniasis and kala-azar, neonatal tetanus, congenital syphilis, intestinal parasites, and cutaneous amebiasis.

Physicians in an extremely busy emergency department see 150 000 children each year, some of whom receive further care in a large holding area. The laboratory and roentgenographic facilities are adequate. The residency program produces graduates with extensive clinical experience, who, during their training, must learn to evaluate and quickly treat numerous sick children using the basic tools of history taking and physical examination rather than relying heavily on the laboratory. This hospital, staffed by a very well-trained faculty and interested and enthusiastic residents, seemed like an ideal setting to initiate our elective in international health.

To increase the benefits to the Honduran pediatricians, the chairman of their department suggested that we send representatives from our faculty who would stay for 2 weeks during the month that our resident was there. Our faculty members would give lectures, make rounds with the Honduran faculty, and assist with the implementation of new procedures, the organization of treatment protocols, and other needs expressed by the host faculty. Several specialty areas that the chairman felt were of highest priority were chosen, and it was within those areas that we would send the appropriate faculty. Project HOPE played a vital role in the initial contact and has continued to assist with that aspect of the program.

We have since established elective alternatives in two English-speaking countries, Jamaica and the Philippines, for our non-Spanish-speaking residents. Those contacts were made through faculty members who were familiar with a particular program abroad. There are a number of US-based voluntary health organizations that may be helpful to other residency programs that are interested in establishing such an elective. Another possibility for establishing contact is through the American Academy of Pediatrics, which is encouraging linkages between state chapters and pediatric societies in developing countries.

The second barrier to starting a program is funding. We were fortunate in that Project HOPE was willing to provide partial support for the program in Honduras. Our electives in the Philippines and Jamaica have been developed with a small departmental subsidy and the philosophy that residents who are truly interested will find monies to cover a portion of their travel and all of their living expenses. Housing accommodations have been obtained with families or within hospital facilities. Such living arrangements have added to the acculturation process of our residents.

Curriculum.—The objectives of this elective program are (1) to give the residents the opportunity to test the depth of their interest in international health as a career option; (2) to see how pediatrics is practiced where resources are scarce; (3) to learn about the health needs and the care that are available for a very large segment of the world's population; (4) to improve basic skills of history taking and physical examination to make diagnoses and commence treatment without the use of sophisticated laboratory tests; (5) to see a large variety of conditions not extensively seen in the United States in a relatively short time, with emphasis on infectious diseases and malnutrition; and (6) to see the application of primary health care in economically depressed urban and/or rural areas and the impact of the Revolution for Child Health as directed by United Nations Children's Fund and the World Health Organization.

In Honduras, our residents spend the majority of the month in the emergency department/holding area of the only tertiary hospital in a country of 3 million people, half of whom are less than 15 years of age. The experience emphasizes acute emergency and stabilization care. In Jamaica,

the month is primarily spent in the pediatric wards of the University of the West Indies. In Manila, the resident's time is divided between the busy ambulatory clinics at the University of Santos Tomas, the Infectious Disease Hospital, and the depressed poverty-ridden areas in and around Manila. There, the residents observe and assist community health workers providing primary health care to their own community neighbors who have had limited education. The essence of that approach is the orientation and application of simple, low-cost, low-technology strategies to improve the health of children.

Selecting the appropriate sites for establishing an elective program should ensure that the conscientious house officer will achieve the defined objectives. The evaluation of our residents was, by necessity, given to the chairman of the department of pediatrics in the host country.

Experience With the Program.—During the inaugural year of the Honduras program, two elective month rotations were available and 1 resident selected this rotation. The enthusiastic message with which she returned was vital in promoting and expanding the elective to six rotations per year and in encouraging other residents to select this elective. In this, the third year of the program, 4 of our 10 senior pediatric house officers have requested the rotation. In 1 month's time in the emergency department/holding area in Tegucigalpa, residents are exposed to a greater variety of acute and serious illnesses than they may see in an entire year in many pediatric programs in the United States. The comments of one of our residents reflects the experiences of all of the residents who have selected this elective:

There was a steady influx of patients with an incredible spectrum of disease waiting outside the emergency room door. Against a background of the ordinary—trauma, dehydration, sepsis, meningitis, pneumonia—came the unusual: neonatal tetanus, tuberculosis, meningitis, snakebite, organophosphate poisoning, kala-azar, infantile spasms, osteogenesis imperfecta, gonococcal conjunctivitis, schizophrenia, encephalocoele, and neonatal AIDS [acquired immunodeficiency syndrome]. The severity of disease was magnified by underlying severe malnutrition and by the long distances which separate the indigent patients from available health care. I remember the quiet, intelligent twelve-year old boy with rheumatic heart disease who presented in severe congestive heart failure which was no longer medically manageable. On his third hospital day his condition was stable, though unimproved, and he seemed unusually quiet. He had come to the hospital alone on the bus, as his family couldn't afford to join him. He died alone that night.

The exchanges our residents have with their Honduran counterparts are reported to be of mutual benefit. Their residents, unable to obtain the most recent journals

or tests, learn some new pathophysiologic concepts, diagnostic approaches, and therapies. Our residents learn that good medical care can be practiced without ordering large numbers of laboratory tests. They return with the concept that the foundation of the art of medicine is complete and detailed history and the performance of a thorough physical examination followed by a thoughtful assessment of the problem, rather than examining computerized printouts of laboratory tests. The faculty has returned with equal enthusiasm, and several are in the process of initiating collaborative research projects with newly found Third-World colleagues.

Those who elect the experience in the Philippines return with some of the same feelings, but they have also been exposed to primary health care as provided in very depressed urban and rural areas. They have seen small groups of neighborhood mothers gathered in tiny living rooms being taught the basis of the United Nations Children's Fund Revolution for Child Health: teaching and supporting traditional health care workers and mothers in the use of low-cost, low-technology strategies to reduce childhood morbidity and mortality. These strategies are exemplified in the acronym GOBI-FFF for growth monitoring, oral rehydration, breast-feeding, immunizations, female education, food supplementation during pregnancy, and family planning.

In Jamaica, our residents learn the management of malnourished infants where Cicely Williams and Derrick Jelliffe did some of their research.¹⁻⁵ They are exposed to illnesses and conditions of Third-World countries but with treatment modalities of those problems provided in a fairly sophisticated setting.

Thus, each experience gives the house officer a view of medicine as practiced in a developing country—a view that serves to broaden their perspectives beyond the confines of life in an academic institution in a developed country, and into a scene that is the norm for a major part of the world.

Conclusions.—We conclude the following regarding our experience with International Health:

1. A variety of electives allow residents the opportunity to explore career options and test the depth of their interest in a variety of areas and disciplines. It is our feeling that this elective program has enhanced the pediatric residency program at the University of Arizona. This current year, the third year since its inception, 4 of the 10 senior house officers have chosen this rotation.

2. The international health elective has provided the resident with the opportunity to learn pediatrics in another setting where the basic skills of history taking and physical examina-

tion are paramount and the laboratory plays only a secondary role; a setting where issues of primary health care are the important considerations, rather than the rarer conditions that are the primary concerns of tertiary centers.

3. The contact with faculty of other universities has provided our faculty the opportunity to exchange epidemiologic, diagnostic, and therapeutic experiences with colleagues in less-sophisticated health care environments and to develop collaborative research projects.

Safety Hazard With Intravenous Pumps

Sir.—The following patient reports document a safety hazard associated with the IMED (model 960) volumetric infusion pump (IMED Corp, San Diego, Calif).

Patient Reports.—PATIENT 1.—A 3-year-old black girl presented with chronic secretory diarrhea. She had been receiving total parental nutrition since the first year of life. During recent hospitalization for suspected central line sepsis, the patient played with the settings on the IMED volumetric infusion pump (model 960), changing the rate to 632 mL/h, thereby self-administering a 120-mL bolus of the 25% dextrose, with 2.5 g of protein per deciliter of the total parenteral nutrition solution. The patient was discovered in an obtunded state, with blood pressure elevated to 146/94 mm/Hg. Findings of an initial laboratory examination were consistent with a hyperosmolar, hyperglycemic, nonketotic state: glucose, 65.5 mmol/L; serum osmolality, 375 mOsm/L; calcium, 2.74 mmol/L; magnesium, 1.15 mmol/L; phosphorus, 2.29 mmol/L; potassium, 5.7 mmol/L; and serum carbon dioxide, 18 mmol/L. Fortunately, the patient completely recovered 1 hour after this incident. Repeated serum chemistry results obtained 4 hours later were normal.

PATIENT 2.—A 2-year-old black boy was admitted for status asthmaticus. He was being treated with an aminophylline dihydrate drip of 1 mg/kg per hour. A level obtained with this dosage was therapeutic at 17.6 mg/L. Subsequently, the patient played with the controls on the IMED volumetric infusion pump (model 960), changing the rate to provide a 300-mg bolus of aminophylline for 40 minutes. The subsequent theophylline level was 46.1 mg/L. Vital signs were remarkable for tachycardia to 169 beats per minute, and the patient was noted to be agitated. Intermittent gastrointestinal charcoal lavage was initiated. He recovered fully without sequelae.

Comment.—We reported these incidents to the IMED Corp. They concluded that the IMED 960 device could not be adapted to protect the control dials from the hands of inquisitive toddlers and noted that model 980 is equipped with a protective mechanism. Clearly, model 960 is not "childproof." We hope this report will alert other health care professionals to this danger.

Adhesive Tape Remover Pads: A Risk to the Newborn?

To the Editor.—1,1,1-Trichloroethane (TCE), also known as methyl chloroform, is a solvent used to remove grease, oil, or wax from metal surfaces. Disposable gauze pads saturated with TCE have found wide acceptance in hospitals as an adhesive tape remover. In the newborn intensive care unit, these pads are used to remove tape from intravenous sites and from around the nose and mouth when nasal cannulae and endotracheal tubes are removed. 1,1,1-Trichloroethane is rapidly absorbed through the lungs, and its clinical effects are related to its concentration in the air.^{1,2} 1,1,1-Trichloroethane levels of 160 ppm have been measured in incubator air following the use of adhesive tape remover pads on an infant mannequin.³ The situation exists, therefore, where appreciable quantities might be inhaled by very small infants. This possibility is enhanced if TCE is applied close to the nares. Furthermore, although TCE absorption through the skin has been described as minimal,⁴ newborn skin is relatively permeable, and percutaneous absorption of a va-

riety of agents is known to be enhanced in the newborn.⁵ Increasingly, we are recognizing that topically applied agents that are nontoxic to adults may be absorbed through the skin in amounts sufficient to produce toxic effects in the newborn infant.⁶

1,1,1-Trichloroethane toxic effects in animals and adults includes depression of the central nervous system and, less commonly, hepatic and renal damage. Sudden cardiac death has been described in relation to short-term exposure,⁷ possibly as a result of TCE sensitizing the myocardium to circulating catecholamines⁸ or decreasing myocardial oxygen uptake.⁹

To our knowledge, systemic absorption of TCE among acutely ill low-birth-weight infants has not been studied. The absence of reports of TCE-related harm, however, provides little reassurance about the safety of this agent in sick newborns. Clinicians are most likely unaware of the content of adhesive tape remover pads, and TCE-induced adverse effects in acutely ill newborns could easily be attributed instead to other drugs or the infant's underlying illness.

We have no evidence that adhesive removal pads saturated with TCE (or other halogenated hydrocarbons) are harmful to newborns. However, the potential for systemic absorption and the known risks of TCE should alert clinicians that the use of these pads may be hazardous in sick, low-birth-weight infants.

Low Serum Complement Levels in Anorexia Nervosa

Sir.—We read the review written by Eichenfield and Johnston,¹ in the May 1989 issue of *AJDC* with great interest, but must disagree with one point, made in Table 1 and in the text. Much of the literature in immunology deals with the abnormalities of anorexia nervosa as if they were the same as the changes seen in malnutrition. Immune abnormalities in the children of Third-World countries, where parasitic infestation abounds and poor hygiene is all too common, are of little relevance to considerations of children of the American middle class, where infection is usually absent. Thus, the two are quite different and should be considered separately.

Several studies of complement levels in individuals with anorexia nervosa have found a decrease in C3,^{2,4} and normal C4.^{2,3,5} Reductions in alternate-pathway components and control proteins^{2,4} have been found as well.

In malnutrition complicated by infection, the most likely cause of hypocomplementemia is a combination of consumption due to ongoing infections and decreased production. The current thinking in anorexia nervosa is that either decreased production of the components³ or a decrease in the complement control proteins C3b inactivator and B1H⁴ is the explanation for the occasional hypocomplementemia found.

5. Kim Y, Michael A. Hypocomplementemia in anorexia nervosa. *J Pediatr*. 1975;87:582-585.

In Reply.—It appears that we do not disagree fundamentally with Drs Sigal and Snyder. Certainly, anorexia nervosa is not the same disease entity as malnutrition in Third-World countries. However, pairing them in the table as complement disorders, due primarily to decreased synthesis, is supported by the experimental evidence that is presently available. As we pointed out, circulating immune complexes and endotoxin in patients with malnutrition could deplete complement, but we believe that the weight of evidence at present favors decreased synthesis as the principal mechanism in both disorders. Although decreased levels of complement control proteins may lead to complement consumption in anorexia nervosa, the primary event is decreased production of these proteins. As we reported, complement abnormalities in both entities are rapidly corrected with appropriate feeding.^{1,2} Perhaps this is the important point.

On Combination Therapy With Benzoate and Piridoxilate

Sir.—It has been amply demonstrated that administration of sodium benzoate moderates hyperammonemia in

children born with genetic defects in the urea cycle,¹ but the efficacy of benzoate therapy has been questioned on the basis of the limited ability of the body to generate the glycine needed to dispose of waste nitrogen as hippurate.² Accordingly, it was recommended that piridoxilate be administered with benzoate to improve the effectiveness of benzoate therapy. Piridoxilate is a European cardiac drug found to stimulate the conversion of benzoate to hippurate in suspensions of hepatocytes, presumably because piridoxilate metabolism gives rise to glyoxylate and, by transamination, glycine.²

Piridoxilate is unavailable in the United States, so we tested the interaction of the active metabolite, glyoxylate, and benzoate. We found glyoxylate to potentiate benzoate toxicity in vivo and both drugs to inhibit pyruvate carboxylase in vitro, by apparently different mechanisms.^{3,4} The combination inhibited pyruvate carboxylase by 80% at 40 μ mol/L of benzoate (Figure), less than half the mean

blood level during therapeutic use.⁵ Inhibition of pyruvate carboxylase was associated with sharply reduced aspartate levels and depressed synthesis of urea.³ Inhibition of pyruvate carboxylase also blocks gluconeogenesis from lactate.⁶ We report these findings to discourage combination therapy with benzoate and piridoxilate, or any other source of glyoxylate, until the benefit of such therapy has been demonstrated in a suitable animal model.

Inhibition of pyruvate carboxylase by glyoxylate and benzoate. Mitochondria (4 to 6 mg of protein) were incubated at 30°C for 10 minutes in 2-mL reaction mixtures containing carbon 14 potassium bicarbonate (0.3 to 0.5 μ Ci, 20 mmol/L) and benzoate and glyoxylate at the concentrations shown. The reactions were acidified with 0.5 mL of 1.6N hydrochloride at 10 minutes and baked to dryness over a steam bath. Acid-stable radiolabeled product was used as the measure of pyruvate carboxylase activity (from Cyr and Tremblay³).

Jejunal Stenosis: A Delayed Complication of Lap-Type Seat Belt Injury

Sir.—Delayed complications of small-bowel injuries after automobile accidents are difficult to diagnose since the clinical and roentgenographic findings are often inconclusive. We report a late complication, jejunal stenosis. To our knowledge, only one similar case has been reported.¹

Patient Report.—A 15-year-old girl presented with severe abdominal and back pain after an automobile accident several hours earlier. She was a rear-seat passenger and was wearing a lap-type seat belt.

The patient was alert, but a severe drop in her hematocrit value to 0.23, a systolic pressure of 80 mm Hg, and a pulse rate of 120 beats per minute were noted. A large hematoma over the lumbosacral area and a "seat belt" shaped bruise over the lower abdomen were present. There was severe abdominal tenderness to palpation, but the abdomen was not distended, with normal bowel sounds.

The patient received several units of blood and fluid replacement. Following stabilization, computed tomography of the abdomen was performed. A subcapsular splenic hematoma, small amount of free intraperitoneal blood, and a Chance fracture of L3 were discovered. The patient's clinical status improved in the hospital with a regimen of supportive therapy and complete bed rest.

On day 11 of hospitalization, the patient developed severe abdominal pain and vomited brown guaiac-positive fluid. Multiple superficial stress ulcers were seen by endoscopic examination. A repeated computed tomographic scan of the abdomen showed evidence of pancreatitis with no pancreatic pseudocyst or duodenal hematoma. The patient improved following appropriate ulcer therapy.

Nine days later, an increase in bile-stained nasogastric drainage was noted. Repeated abdominal roentgenograms revealed a dilated loop of bowel in the epigastric area interpreted as ileus secondary to pancreatitis and less likely related to early small-bowel obstruction (Fig 1). An upper gastrointestinal tract series was performed the next day and showed complete obstruction at the proximal jejunum. At the obstruction, a smooth, symmetrically narrowed segment of jejunum was seen, characteristic of extrinsic compression (Fig 2).

On exploratory laparotomy, two stenotic segments of jejunum were found, and the corresponding mesentery was fibrotic and devascularized. The proximal segment was matted with other loops of bowel in the right lower quadrant. Resection of the stenotic segments with end-to-end anastomosis and appendectomy were performed. The microscopic examination of the stenotic segments of jejunum revealed fibrosis of the bowel wall and mesentery, consistent with bowel infarction. No definite thrombi were seen within the vessels and there was no evidence of vasculitis. The patient had an uneventful recovery and was discharged 12 days after the surgery with a body cast.

Comment.—Lap-type seat belts are less protective than the three-point combined lap and shoulder belt restraint. With the lap-type belt, injuries occur in the abdomen, pelvis, and lumbar spine.² Although solid viscera are more prone to be injured in blunt abdominal trauma, 5% to 10% of such injuries involve the small bowel and mesentery.³ The small bowel and mes-

Fig 1.—Plain abdominal roentgenogram demonstrating a dilated loop of small bowel in the epigastrium. Chance fracture of L3 is seen.

Fig 2.—Roentgenogram from upper gastrointestinal tract series showing the markedly dilated proximal jejunum that becomes tubular symmetrically narrowed at the side of obstruction.

entery are more vulnerable to injury because of the anterior midline location of the small bowel where the impact is the greatest. The mechanism of injury is related to shearing and tearing forces exerted by sudden de-

celeration while the victim's pelvis and hips are fixed to the car seat.⁴ Points of fixation of the mesentery are especially prone to damage, such as the ligament of Treitz, the terminal ileum, adhesions from previous surgery, hernias, and shortened mesentery (often found in Crohn's disease).³⁻⁵

Delayed complications of small-bowel trauma include ischemic bowel, perforation, enterocutaneous or colcutaneous fistulas, and small-bowel stenosis with obstruction.⁶ A considerable ischemic insult to the bowel occurs when mesenteric vessels are torn. Severe devascularization and devitalization causes gangrene with subsequent bowel perforation. In a partially infarcted segment of bowel, there is revascularization and the development of fibrotic changes, resulting in stricture formation and bowel obstruction.^{7,8}

Bowel obstruction as a late complication of blunt abdominal trauma has been described in connection with adhesions and posttraumatic hernias.^{9,10} The diagnosis of bowel and mesenteric injuries might not be suspected in a patient with few clinical symptoms or in those patients treated for severe nonabdominal injuries. An association of lumbar spine fractures with intestinal injuries has been described.¹¹

The "seat belt" sign (contusion and ecchymosis in the abdominal area), when present, should alert the clinician and radiologist to the possibility of intestinal injury. Close surveillance for delayed complications is warranted since mortality and morbidity are primarily related to a delay in diagnosis.

Perinatal Abnormalities and Subhypothalamic Bright Spot on Magnetic Resonance Imaging in Pituitary Dwarfs

Sir.—The survey results on magnetic resonance imaging (MRI) in patients with idiopathic pituitary dwarfism as reported by Root et al¹ were interesting and warrant further observations. The authors demonstrated that MRI in two patients with pituitary dwarfism without asphyxia at birth (one had panhypopituitarism with intact posterior function, and the other had central hypothyroidism) had a signal of high intensity near the optic tract.^{2,3} A small pituitary gland and an unclear defined pituitary stalk were also observed.⁴

To ascertain that the hypopituitary

state was a result of an insult to the pituitary stalk, we compared the T₁-weighted MRI findings of the hypothalamic-pituitary structure in two groups, a total of 14 patients, of idiopathic pituitary dwarfs. The two groups were the following: those with perinatal abnormalities were group 1 (5 boys and 2 girls) (6 had had asphyxia at birth and 1, dystocia with vacuum extraction); those who had had a normal perinatal period were group 2 (6 boys and 1 girl).

A hypoplastic pituitary gland (<2.5 mm in height) was observed in all patients in group 1. Six of them had MRI scans that revealed high-signal intensity near the optic tract (2.5- to 3.0-mm nodule size at the median eminence), suggesting posterior pituitary ectopia⁵ and a hypoplastic pituitary stalk (<0.6 mm wide). The remaining patient in group 1 showed an intrasellar posterior bright spot⁶ with a hypoplastic stalk and a minimal decrease in the size of the anterior pituitary gland.

In all patients in group 2, however, an intrasellar posterior pituitary bright spot with a normal-sized pituitary gland was observed. No patient with a history of perinatal asphyxia was found to have a normal pituitary gland on their MRI scans.

These data reinforced the report of Root et al that the hypopituitary state is due to an insult to the pituitary stalk. However, our data suggested that "ectopic" posterior pituitary may be common in the idiopathic pituitary dwarfs with perinatal abnormalities, but not in those without abnormalities. We may therefore make the sug-

gestion from these findings that idiopathic pituitary dwarfism can be further classified into two or more subgroups—one due to perinatal asphyxia and the others not.

Leads From the MMWR

Morbidity and Mortality Report
Centers for Disease Control, Atlanta

Current Trends, Measles—United States, 1988

MMWR. 1989;38:601-605

IN 1988, a provisional total of 3411 measles cases was reported to the Division of Immunization, Center for Prevention Services, CDC, 7% less than the 3652 cases reported during the same period in 1987 (Figure 1).¹ The overall incidence rate for 1988 was 1.4 cases per 100,000 population. Nine states reported greater than or equal to 100 cases and accounted for 2802 (82.1%) cases: California (836), Pennsylvania (542), New Jersey (402), Texas (287), Virginia (239), Florida (170), Colorado (117), Ohio (109), and New Hampshire (100). Seven states had incidence rates greater than 2.0 per 100,000 population: Montana (10.7), New Hampshire (9.2), New Jersey (5.2), Pennsylvania (4.5), Virginia (4.0), Colorado (3.5), and California (3.0). Thirty-six states and 211 (6.7%) of the nation's 3138 counties reported measles cases.

A total of 3176 (93.1%) cases met the standard clinical case definition for measles,* and 1001 (29.3%) were serologically confirmed. The usual seasonal pattern was observed with cases peaking during weeks 18-25 (May and June).

Eighty-seven (2.6%) cases were known to be imported from other countries. An additional 126 (3.7%) cases were epidemiologically linked to imported cases within two generations. Fifty-seven outbreaks (five or more epidemiologically linked cases) were reported and accounted for 89.3% of all cases. Six outbreaks had greater than 100 cases and accounted for 52.7% of all reported cases. Most outbreaks occurred among school-aged children. The largest outbreak (611 cases) occurred in Los Angeles among unvaccinated preschool-aged children.

The incidence rate of measles decreased between 1987 and 1988 for 0-4-, 5-9-, and 10-14-year-olds, and increased in 15-19- and 20-24-year-olds. The highest incidence rate (5.8 per 100,000) occurred in 15-19-year-olds (Table 1).

Complications were reported in 408 (12.0%) cases. Otitis media was reported in 183 (5.4%); diarrhea, in 128 (3.8%); pneumonia, in 93 (2.7%); and encephalitis, in four (0.1%). Three

hundred sixty-eight (10.8%) persons were hospitalized. Three measles-attributable deaths were reported (case-fatality rate: 0.9 deaths per 1000 cases).

Of the 2179 (63.9%) patients for whom setting of transmission was reported, 871 (40.0%) acquired measles in primary or secondary schools; 267 (12.3%), in colleges or universities; 553 (25.4%), at home; 127 (5.8%), in medical settings; 69 (3.2%), in day care; and 292 (13.4%), in a variety of other settings.

A total of 1548 (45.4%) patients had been vaccinated on or after the first birthday (Table 2), including 729 (21.4%) who were vaccinated at 12-14 months of age. One thousand eight hundred sixty-three (54.6%) persons were not vaccinated on or after the first birthday. Of these, vaccination would have been routinely indicated** for 803 (23.5%). Six hundred twenty-eight (18.4%) cases occurred in persons for whom vaccine was not routinely indicated, and 432 (12.7%) were unvaccinated for other reasons.

Of the 3411 reported cases, 1942 occurred among school-aged children. Of these, 1339 (68.9%) had been appropriately vaccinated. Most of the vaccine failures occurred in persons 12-19 years of age (Figure 2).

Reported by: Div of Immunization, Center for Prevention Svcs, CDC (MMWR Vol 38 No. 35).

CDC Editorial Note: Since 1983, the number of reported measles cases increased annually until 1986, then decreased in 1987 and slightly in 1988 (Figure 1). In 1988, the age distribution of cases was similar to those in previous years. As in previous years, primarily two types of outbreaks occurred: those among highly vaccinated (vaccine coverage greater than 90%) school-aged children and those among unvaccinated preschool-aged children.²

The epidemiology of measles points to two major impediments to measles elimination—unvaccinated preschool-aged children, allowing large outbreaks in inner-city areas, and vaccine failures, accounting for outbreaks in highly vaccinated school-aged popula-

tions. Therefore, in January 1989, the Immunization Practices Advisory Committee (ACIP) issued revised recommendations.³ First, ACIP lowered the age for routine measles vaccination in inner-city areas to as low as 9 months so that children would be vaccinated before they could be exposed to measles, and coverage would therefore be increased. Second, ACIP recommended that, for outbreaks in schools, previously vaccinated persons in specific target groups be revaccinated in affected schools and unaffected schools at risk for transmission. The groups targeted for revaccination are persons vaccinated before 1980 or vaccinated at 12-14 months of age. The rationale for choosing the 1980 date has been described.³ Data from four recent outbreak investigations have shown that persons vaccinated before 1980 are at increased risk for measles (Table 3). This is believed to be due primarily to a higher rate of failure of initial seroconversion for persons vaccinated before that time. Although children vaccinated between 12 and 14 months of age are at higher risk than are children vaccinated at older ages, only a minority of children with measles in most outbreaks have been vaccinated between these ages.¹

Implementation of these new outbreak-control recommendations during 1989 has been expensive because of the large number of outbreaks and cases. In the first 26 weeks of 1989, 8553 cases were reported, a 392% increase over the same period in 1988. More than 90 outbreaks have been reported; most have occurred in secondary schools and colleges. Seventy-one colleges have reported at least one case of measles. The largest outbreak has occurred in Houston, with greater than 1700 cases, primarily among unvaccinated preschool-aged children. Several states have spent several hundred thousand dollars each to revaccinate young adults in secondary schools and colleges.

Because of continued outbreaks among school-aged children, in May 1989, the ACIP decided to recommend a routine two-dose measles vaccination schedule. The second dose will be administered at entry to kindergarten

or first grade (children 4-6 years of age). A two-dose schedule will decrease primary vaccine failures and thus the number of susceptibles and measles outbreaks in school-aged children. In addition, outbreak-control measures will be simplified. Detailed recommendations for this schedule and outbreak control are being formulated and will be published in the fall of 1989. Until then, the previously published schedules and recommendations should be followed. The American Academy of Pediatrics has also developed a routine two-dose measles vaccination schedule, which recommends that the second dose be given at entry to middle or junior high school.⁷

The two-dose schedule will not affect outbreaks in inner-city areas among unvaccinated preschool-aged

children. Prevention of such outbreaks requires intensive efforts directed at increasing age-appropriate immunization levels, which are being initiated by CDC and state and local health departments. These include activities in service delivery, assessment, information/education, operational research and surveillance. The two-dose schedule and intensive efforts to raise age-appropriate immunization levels should facilitate the goal of measles elimination in the United States.

Aquarium-Associated *Plesiomonas shigelloides* Infection—Missouri

MMWR. 1989;38:617-619

IN JULY 1988, a community hospital in southeastern Missouri reported isolating *Plesiomonas shigelloides* from the stool of a 14-month-old girl with watery diarrhea (no blood or mucus) and fever. Her highest recorded rectal temperature was 102 F (38.9 C). Her stool was negative for *Campylobacter*, *Salmonella*, *Shigella*, *Yersinia*, *Aeromonas*, and rotavirus. The child was treated with trimethoprim/sulfamethoxazole, and her illness resolved after 5 days.

The child had consumed no shellfish and had never traveled more than 80 miles from her home. She had consumed water only from the municipal system and recently had waded in two area lakes. She attended a day-care center, but no other children in her age group were reported ill. The child did not have an aquarium or other close association with animals. However, 1 evening each week, the child stayed in the home of a babysitter who kept piranhas in an aquarium. When the aquarium was cleaned, the water was poured into the bathtub. The child routinely was bathed in the bathtub before going home. The babysitter reported that the child could have been bathed immediately after the aquarium water had been poured into the bathtub.

P. shigelloides was isolated from samples of aquarium water submitted

to the State Public Health Laboratory. However, plasmid studies were not performed, and it was not determined whether the bacterial strain isolated from the child's stool was identical to that isolated from the babysitter's aquarium.

To estimate the prevalence of *P. shigelloides* in tropical fish tanks, investigators from the Missouri Department of Health (MDH) surveyed aquarium water samples from several sites in Missouri (Table 1). Samples were taken from 18 aquariums, including at least two tanks from each of Missouri's six regional health districts. *P. shigelloides* was isolated from four (22%) of the 18 tanks. The four tanks were located in three different pet shops: two in central Missouri and one in eastern Missouri. Employees of the three pet shops reported no health problems in the fish in the culture-positive tanks.

MDH advised managers of all surveyed pet shops to have employees wash hands after contact with aquarium water or fish. No special precautions were recommended to managers of shops from which *P. shigelloides* was isolated. In addition, the babysitter was advised to clean the tub thoroughly using chlorine bleach after discarding the aquarium water and before using the tub for bathing.

Reported by: PS Tippen, A Meyer, EC Blank,

DrPH, State Public Health Laboratory, HD Donnell, Jr, MD, State Epidemiologist, Missouri Dept of Health. Div of Field Svcs, Epidemiology Program Office, CDC. (*MMWR* vol 38, No. 365)

CDC Editorial Note: *P. shigelloides*, a gram-negative bacterial rod, is an opportunistic pathogen in the immunocompromised host and has been suspected to cause diarrheal illness in normal hosts.^{1,2} However, the organism failed to produce illness in volunteer feeding studies, and its role as an enteric pathogen remains unproven.¹ Persons with *P. shigelloides* infection typically describe a self-limited diarrhea, sometimes with blood and mucus in the stool; appropriate antibiotic therapy appears to shorten the duration of illness.^{3,4} *P. shigelloides* can also cause cellulitis and septicemia.

This organism has been isolated from surface water, the gut of freshwater fish, and many animals (including dogs and cats) and is particularly common in tropical and subtropical habitats.⁵ In humans, most isolates have been from stools of patients with diarrhea who live in tropical and subtropical regions of Asia, Africa, and Australia; isolations from Europe and the United States have been rare and usually associated with foreign travel or consumption of raw oysters.^{3,6}

Although no other *P. shigelloides* gastrointestinal infections associated with aquarium water have been re-

ported, the frequency of *P. shigelloides* in pet shop aquariums reported here suggests this could be a source of this rarely recognized infection. Basic precautions, such as handwashing after contact with aquarium water and preventing the contamination of potable or bathing water by aquarium water, should decrease transmission of potentially pathogenic microorganisms from aquarium water.

Publication of Guide for Developing Policies for HIV-Infected Students and School Staff

MMWR. 1989;38:614-615

THE NATIONAL ASSOCIATION of State Boards of Education (NASBE) is one of 20 national organizations that receive assistance from CDC to help schools provide effective health education programs to prevent the spread of human immunodeficiency virus (HIV). NASBE has published a guide that CDC commends to its readers: *Someone at School Has AIDS: A Guide to Developing Policies for Students and School Staff Members Who Are Infected with HIV*.

To develop the guide, NASBE convened experts in medicine, public health, education, and law* and has

recommended scientifically and legally based policy statements that local and state departments of education can use in developing policies for HIV-infected students and staff. The guide addresses infection control, HIV-infected students and school staff, confidentiality, and HIV-antibody testing. The guide also includes resources for further information about HIV education, discrimination, disease reporting, policymaking, and crisis management.

Copies of the guide are available from NASBE, Publications Department, 1012 Cameron Street, Alexandria, VA 22314; telephone (703) 684-4000.

*Representatives of the following organizations participated in developing and/or reviewing the guide: American Academy of Pediatrics, American Association of School Administrators, American Bar Association, American Federation of Teachers, American Medical Association, Association of State and Territorial Health Officials, CDC, Council for Exceptional Children, Council of Chief State School Officers, Intergovernmental Health Policy Project, Michigan Department of Education, National Association of Elementary School Principals, National Association of School Nurses, National Association of Secondary School Principals, National Congress of Parents and Teachers, National Education Association, National School Boards Association, U.S. Department of Education, and U.S. Department of Justice.

Enterovirus Surveillance—United States, 1989

(*MMWR* 1989;38:563)

NONPOLIO ENTEROVIRUS (NPEV) surveillance data show that isolates from March through May predict the types likely to be isolated in July through December, which includes the peak enterovirus season.¹ State virology laboratories have reported to CDC 31 NPEV isolates obtained from patients in the United States from March through May 1989. Coxsackievirus B5 was isolated most frequently (16 isolates), followed by echovirus 6 (two isolates), and coxsackievirus B3, coxsackievirus A3, and echovirus 9 (one each); 10 isolates were reported as untyped enteroviruses.

Of the 946 NPEV isolates reported in 1988, the six most common were echovirus 11 (18.6%), echovirus 9 (14.1%), coxsackievirus B4 (10.6%), coxsackievirus B2 (9.2%), echovirus 6 (6.2%), and coxsackievirus B5 (5.1%). In 1988, these six NPEV types rep-

resented 64% of the total enterovirus isolates.

Reported by: State virology laboratory directors. Respiratory and Enterovirus Br, Div of Viral and Rickettsial Diseases, Center for Infectious Diseases, CDC. (*MMWR* vol. 38, no. 32)

CDC Editorial Note: Enteroviruses are a group of 65 different common agents that cause 10-20 million mild upper respiratory infections in the United States every year. Enteroviruses are also responsible for tens of thousands of hospitalizations for aseptic meningitis each year. Knowledge of the common enterovirus subtypes may assist diagnostic laboratories in more rapidly identifying enterovirus isolates and assist public health officials in recognizing outbreaks of enteroviral disease.

Since 1970, state health department laboratories have reported on enterovirus serotypes to CDC approximately 6-8 weeks after specimens are submit-

ted for identification. From 1970 through 1983, the six most common isolates in March through May accounted for an average of 59% of the isolates in July through December, and for this period in 1984-1988, for 50%-58% of the isolates.

The NPEV isolates reported in early 1989 included many coxsackievirus B5 and several of three other types; however, the limited number of these four types makes it impossible to predict at this time that they will be common isolates in 1989. The top six isolates reported in 1988 and each of the four isolates reported in March through May 1989 were in the 15 most frequent isolates for 1970-1983.¹

NEW FROM McNEIL

**Pedia
Profen™**

Ibuprofen Suspension 100 mg/5 ml

A new therapeutic alternative for fever

Antipyretic efficacy

In children with temperatures greater than 102.5°F, ibuprofen 10 mg/kg is more effective than ibuprofen 5 mg/kg or acetaminophen 10 mg/kg.¹

PediaProfen is indicated for the reduction of fever in children 6 months and older.

Longer duration of action than acetaminophen for fever^{1,2}

Ibuprofen 10 mg/kg provides up to 8-hour relief. That means fewer interruptions in the family's work, school, or sleep schedules.

Safety profile*

See brief summary of Prescribing Information. Significant adverse effects are reported with NSAIDs. Serious as well as minor side effects can occur with long-term use of high-dose ibuprofen. In clinical studies with over 400 pediatric patients, no significant adverse reactions were reported during short-term therapy for fever.²

Pleasant-tasting

Designed for compliance; well liked by patients in clinical studies.²

Introducing Rx

Pedia Profen™

Ibuprofen Suspension
100 mg/5 ml

New **PediaProfen**[™]

Ibuprofen Suspension 100 mg/5 ml

The following is a brief summary only. Before prescribing, see complete prescribing information in **PediaProfen** labeling.

INDICATIONS AND USAGE: **PediaProfen** is indicated for the reduction of fever in patients aged 6 months and older, and for the relief of mild-to-moderate pain in patients aged 12 years and older.

CLINICAL PHARMACOLOGY: Controlled clinical trials comparing doses of 5 and 10 mg/kg ibuprofen and 10-15 mg/kg of acetaminophen have been conducted in children 6 months to 12 years of age with fever primarily due to viral illnesses. In these studies there were no differences between treatments in fever reduction for the first hour and maximum fever reduction occurred between 2 and 4 hours. Response after 1 hour was dependent on both the level of temperature elevation as well as the treatment. In children with baseline temperatures at or below 102.5°F both ibuprofen doses and acetaminophen were equally effective in their maximum effect. In those children with temperatures above 102.5°F, the ibuprofen 10 mg/kg dose was more effective. By 6 hours children treated with ibuprofen 5 mg/kg tended to have recurrence of fever, whereas children treated with ibuprofen 10 mg/kg still had significant fever reduction at 8 hours. In control groups treated with 10 mg/kg acetaminophen, fever reduction resembled that seen in children treated with 5 mg/kg of ibuprofen, with the exception that temperature elevation tended to return 1-2 hours earlier.

CONTRAINDICATIONS: **PediaProfen** should not be used in patients who have previously exhibited hypersensitivity to ibuprofen, or in individuals with all or part of the syndrome of nasal polyps, angioedema and bronchospastic reactivity to aspirin or other nonsteroidal anti-inflammatory agents. Anaphylactoid reactions have occurred in such patients.

WARNINGS: Risk of GI Ulceration, Bleeding and Perforation with NSAID Therapy. Serious gastrointestinal toxicity such as bleeding, ulceration, and perforation, can occur at any time, with or without warning symptoms, in patients treated chronically with NSAID therapy. Although minor upper gastrointestinal problems, such as dyspepsia, are common, usually developing early in therapy, physicians should remain alert for ulceration and bleeding in patients treated chronically with NSAIDs even in the absence of previous GI tract symptoms. In patients observed in clinical trials of several months to two years duration, symptomatic upper GI ulcers, gross bleeding or perforation appear to occur in approximately 1% of patients treated for 3-6 months, and in about 2-4% of patients treated for one year. Physicians should inform patients about the signs and/or symptoms of serious GI toxicity and what steps to take if they occur.

Studies to date have not identified any subset of patients not at risk of developing peptic ulceration and bleeding. Except for a prior history of serious GI events and other risk factors known to be associated with peptic ulcer disease, such as alcoholism, smoking, etc., no risk factors (e.g., age, sex) have been associated with increased risk. Elderly or debilitated patients seem to tolerate ulceration or bleeding less well than other individuals and most spontaneous reports of fatal GI events are in this population. Studies to date are inconclusive concerning the relative risk of various NSAIDs in causing such reactions. High doses of any NSAID probably carry a greater risk of these reactions, although controlled clinical trials showing this do not exist in most cases. In considering the use of relatively large doses (within the recommended dosage range), sufficient benefit should be anticipated to offset the potential increased risk of GI toxicity.

PRECAUTIONS: General: Blurred and/or diminished vision, scotomata, and/or changes in color vision have been reported. If a patient develops such complaints while receiving **PediaProfen**, the drug should be discontinued and the patient should have an ophthalmologic examination which includes central visual fields and color vision testing.

Fluid retention and edema have been reported in association with ibuprofen, therefore, the drug should be used with caution in patients with a history of cardiac decompensation or hypertension.

PediaProfen, like other nonsteroidal anti-inflammatory agents, can inhibit platelet aggregation, but the effect is quantitatively less and of shorter duration than that seen with aspirin. Ibuprofen has been shown to prolong bleeding time (but within the normal range), in normal subjects. Because this prolonged bleeding effect may be exaggerated in patients with underlying

hemostatic defects, **PediaProfen** should be used with caution in persons with intrinsic coagulation defects and those on anticoagulant therapy.

Patients on **PediaProfen** should report to their physicians signs or symptoms of gastrointestinal ulceration or bleeding, blurred vision or other eye symptoms, skin rash, weight gain, or edema.

In order to avoid exacerbation of disease of adrenal insufficiency, patients who have been on prolonged corticosteroid therapy should have their therapy tapered slowly rather than discontinued abruptly when ibuprofen is added to the treatment program.

The antipyretic and anti-inflammatory activity of **PediaProfen** may reduce fever and inflammation, thus diminishing their utility as diagnostic signs in detecting complications of presumed noninfectious, noninflammatory painful conditions.

Since ibuprofen is eliminated primarily by the kidneys, patients with significantly impaired renal function should be closely monitored and a reduction in dosage should be anticipated to avoid drug accumulation. Prospective studies on the safety of ibuprofen in patients with chronic renal failure have not been conducted.

Safety and efficacy of **PediaProfen** in children below the age of 6 months has not been established.

Pregnancy: Reproductive studies conducted in rats and rabbits at doses somewhat less than the maximal clinical dose did not demonstrate evidence of developmental abnormalities. However, animal reproduction studies are not always predictive of human response. As there are no adequate and well-controlled studies in pregnant women, this drug should be used during pregnancy only if clearly needed. Because of the known effects of nonsteroidal anti-inflammatory drugs on the fetal cardiovascular system (closure of ductus arteriosus), use during late pregnancy should be avoided. As with other drugs known to inhibit prostaglandin synthesis, an increased incidence of dystocia and delayed parturition occurred in rats. Administration of **PediaProfen** is not recommended during pregnancy.

ADVERSE REACTIONS: The most frequent type of adverse reaction occurring with ibuprofen is gastrointestinal. In controlled clinical trials, the percentage of adult patients reporting one or more gastrointestinal complaints ranged from 4% to 16%.

Adverse reactions occurring in 3% to 9% of patients treated with ibuprofen: nausea, epigastric pain, heartburn, dizziness, rash. *Adverse reactions occurring in 1% to 3% of patients:* diarrhea, abdominal distress, nausea and vomiting, indigestion, constipation, abdominal cramps or pain, fullness of GI tract, headache, nervousness, pruritus, tinnitus, decreased appetite, edema, fluid retention (generally responds promptly to drug discontinuation). Still other reactions (less than 1 in 100) have been reported, and are detailed in the full summary of prescribing information.

DOSAGE AND ADMINISTRATION: Shake well prior to administration.

Fever Reduction in Children 6 months to 12 years of age:

Dosage should be adjusted on the basis of the initial temperature level (See CLINICAL PHARMACOLOGY for a description of the controlled clinical trial results). The recommended dose is 5 mg/kg if the baseline temperature is less than 102.5°F or 10 mg/kg if the baseline temperature is greater than 102.5°F. The duration of fever reduction is generally 6-8 hours and is longer with the higher dose. The recommended maximum daily dose is 40 mg/kg.

Mild to moderate pain: 400 mg every 4 to 6 hours as necessary for the relief of pain in adults.

In controlled analgesic clinical trials, doses of ibuprofen greater than 400 mg were no more effective than 400 mg dose.

HOW SUPPLIED: **PediaProfen** Ibuprofen Suspension 100 mg/5 ml (teaspoon)—

orange, berry-vanilla flavored

Bottles of 4 oz (120 ml)..... NDC 0045-0469-04
Bottles of 16 oz (480 ml)..... NDC 0045-0469-16

SHAKE WELL BEFORE USING. Store at room temperature.

Caution: Federal law prohibits dispensing without prescription.

Being Just a Husband Is No Fun

E. Richard Stiehm, MD

One of our stalwarts on the Editorial Board has had a unique experience in the last few years; he has been a transcontinental spouse. In one of his two lives, as he so aptly describes, he has learned how the "other half" feels to be "the spouse of . . .". His article has currency, not only for the experience itself and its reflection of some marriages today, but because such experience will become commonplace in the future. More and more women have entered medicine and other professional careers and are achieving hierarchical status within their chosen fields. Their male spouses will now have to cope, as our female spouses have for decades, with a quite different role than that of the stereotypic dominant male, so prominent in American conception.

My wife, Shirley, and I attended a retreat for first-year freshman medical students not too many years ago. I was privileged to be a member of the small break-out group that consisted of spouses and so-called significant others of the medical students. To my amazement and education, the majority were male (correspondingly, most of the students attending the retreat were female), and the attitudes displayed echoed what I had heard female spouses of the faculty saying for years. For example, one male businessman said, "Do you mean that if she wants to take a residency in Seattle, I'd have to give up my business and follow her? . . . Hell, no!" Perhaps he would be like Dr Stiehm and conduct a Los Angeles-Tucson-to-Seattle marriage. Another complained, "At every party we go to, all they talk about is medicine! Don't they have any other interests?" And on through the day.

On reflection, Shirley and I realized that medical marriages are in for some surprises in the future. Dr Stiehm's experience is just the forerunner of many like it in the future. We will have to find new ways to make relationships work and to be sustained over the years. Men will have to learn to be secondary in interest to friends and colleagues of their successful female spouses. Men will have to learn to tolerate highly technical cocktail-party and dinner-party talk outside their sphere of knowledge, and interest, and scope.

We are truly in for a brave new tomorrow. Dr Stiehm's firsthand description will be recognized by many today as pertinent and will be a blueprint for the future. May all have the wisdom and humor of Judy and Dick Stiehm!—ED

In Los Angeles, Calif, I am taken seriously. In Miami, Fla, I am not. The contrast is illuminating and humorous, but not entirely pleasant.

At home in Los Angeles, my identity is as a physician and teacher. I take care of kids with acquired immunodeficiency syndrome, teach pediatrics at UCLA Medical School, write papers, give lectures, and direct a research laboratory. Others regard me, I hope, as a useful, contributing member of society.

My main problem is that a year ago, my wife Judy, a political science professor, became provost of a large state university in Miami. So we have the proverbial bicoastal marriage, and I try to get to Miami twice a month.

Don't get me wrong, I'm not jealous or anything. I'm proud of her and know how hard she has worked through many moves, three children, and the barriers working women of her generation had to face.

My life changes drastically in Miami. I become a nonperson, without a work identity. Socially, however, I can't complain. We attend concerts and plays, parties and receptions, lectures and sports events. But sometimes I can't help feeling like Prince Philip—the charming consort, who lives in his wife's reflected glory.

This life is like a spicy Chinese egg roll: tasty at first, often hard to digest, but definitely not suitable for a daily menu. Let me describe a weekend last December, for example.

Judy wanted me to come that weekend because she was giving a Christmas party that would include her colleagues and friends in the Miami establishment. She met me at the airport Friday afternoon and was frantic because my flight was over an hour late, as usual. She looked relieved that I hadn't checked any luggage.

I drove, with her directions, to the Merrick House in Coral Gables, Fla, an historic home that would easily accommodate the 200 guests. She needed to use the time to check the guest list. Her secretary had carefully prepared cards

on each guest, with the spouse's first name on them.

Judy instructed me on whom I should be sure to talk with, and who was who in the university and the community. I told her it was an exercise in futility because I would forget their names as soon as she told them to me. She said that was OK, it was a good review for her.

When we arrived, there wasn't much for me to do, since the student caterers had things well under control, and Judy ("Dr Stiehm") was involved in giving them last-minute instructions.

So I picked up the *Miami Herald* and noticed that her boss, the university president, was quoted as describing his job as "like juggling five balls, while on roller skates, perched on top of a flag pole." I pointed this out to Judy, who immediately dispatched me to buy balls, skates, and a small flag pole for a gag gift to give her boss at the party. At last I felt useful.

The party was a grand success. People told me what a good job "Judith" was doing and asked me, "By the way, what do you do in Miami?" I had to confess,

90024-1752 (Dr Stiehm)

"Nothing, just visiting my wife." Then they asked me when I was moving there, away from the smog and crime of Los Angeles. Several asked if we played mixed doubles.

The next day, Judy's old friend, Betty Friedan, came to town to give a talk. Betty wanted to see Judy's office, so we went there first, with me tagging along, listening to them discuss where the women's movement is now and whether the press would cover the lecture. When we got there, Betty and I admired the paintings, the teak desks, the thick carpets, and the balcony. At least Judy's 12-hour days were conducted in civilized surroundings.

Then it was time for Betty's speech. There was a good crowd, about 190 women and 10 men. "It's an overflow," said Judy as we arrived. She was going to introduce Betty, so they went up front, while I took a seat in the back.

Betty covered what couples can do to cope with two-career marriages in the 1980s. One inevitable result, she said, was the birth of the commuter marriage. I consoled myself that we were on the cutting edge of a trend, even in our 50s.

Afterward there were punch and

cookies for everybody. Betty and Judy were the two stars of the show, the ones that people surrounded. I got a drink and looked around for someone to talk with. Almost by a tribal instinct, I started talking with the only other man at the reception. He was a dour associate professor who criticized the speech, the acoustics, even the cookies. He wanted to know why I came to the lecture. After I told him that my wife was the provost, he suddenly became very interested in me, especially in telling me what needed to be done about the university's problems—higher faculty salaries, bigger offices, a lighter teaching load, better parking, things like that. He hinted I should pass these insights on to my wife.

Once he wandered off, I found myself alone. I had the feeling that people were looking through me or over my shoulder. Finally, two nice older ladies came over to say hello to me. I had become an expert at small talk by then, and we had a pleasant conversation. I found out that they were co-owners of a pet boardinghouse. (Neither was named Muriel.) They knew who my wife was and commented on how "pretty" she was. Then came the familiar question: "When will

you be moving to Miami?"

Whenever I say it—that I have no plans to move to Miami—the reaction is pretty much the same: surprise and disappointment, with a little disapproval thrown in. These ladies were no different and quickly changed the subject.

"Does your wife own a pet?" one of the women asked. The other added, "She must travel a lot. Doesn't she need a place to keep her pet?" I couldn't help wondering if that was the only reason they were talking with me. I said, "No, I'm sorry. She doesn't have a pet." But to cushion the blow, I added that if she did get one, I would tell her about their boardinghouse. Then I introduced them to Judy and Betty. They were so pleased that afterward they thanked me for the introduction.

So went the weekend in Miami. Others have been more or less like that one. Now I know how many wives feel at their husbands' business dinners or medical conventions.

It's a little hard on my male ego being just a husband. Maybe that's why I haven't moved to Miami. All in all, it's better to be the big wheel than the big wheel's spouse.

Age-Related Patterns of Violent Death, Cook County, Illinois, 1977 Through 1982

Katherine K. Christoffel, MD, MPH; Nora K. Anzinger, RN; David A. Merrill

• To clarify age-related patterns of violent death in childhood, a study was undertaken of medical examiner records concerning 437 deaths of Cook County, Illinois residents, aged younger than 15 years, who died from 1977 through 1982, and whose deaths were ruled as homicides or of an undetermined manner. Males outnumbered females after the age of 1 year. Black children were overrepresented. Perpetrators were usually parents for victims aged younger than 5 years and others for victims aged 5 years or older. Different circumstances of death characterized victims who were younger (mainly beatings) and older (mainly gunshots). Incidence was associated with urban residence and poverty, and it was highest among the youngest and oldest children. Striking differences were found in death rates for age subgroups within standard age groupings (eg, 19.77/100 000 for 1 and 2 years and 6.35/100 000 for 3 and 4 years). Different geographic areas had the highest rates for younger and older victims. We conclude: (1) Separate strategies are needed to protect the two groups at highest risk for homicide: black children aged younger than 3 years and older than 11 years in poor urban areas. (2) Standard homicide reporting practices should include narrow age groupings. (3) Age-related patterns of child homicide must be considered in the planning of prevention trials. (4) Research is needed to clarify why children of different ages are at different risks in different communities.

(AJDC. 1989;143:1403-1409)

Accepted for publication May 22, 1989.

Presented in part at the annual meeting of the Ambulatory Pediatric Association, Anaheim, Calif, April 30, 1987, and at the First National Symposium on Child Abuse Fatalities, Chicago, Ill, July 14, 1987.

Reprint requests to Division of General and Emergency Pediatrics, Department of Pediatrics, Northwestern University School of Medicine, Children's Memorial Hospital, 2300 Children's Plaza, Box 46, Chicago, IL 60614 (Dr Christoffel).

Violence, including assault and child abuse and neglect, has become one of the leading causes of death in childhood and adolescence.^{1,2} Preventive approaches will grow from the understanding of the epidemiologic features of homicides. Published reports have provided information on varying numbers of victims, in various time periods, age ranges, and settings.³⁻¹⁹ Cook County, Illinois, has an incidence of violent child death that is sufficiently high so that several recent years have provided an adequate number of deaths to describe clearly contemporary patterns. The county includes urban, suburban, and rural areas, and it has had its Office of the Medical Examiner, (Chicago, Ill) staffed by forensic pathologists since 1977. A 6-year retrospective study of violent child deaths was undertaken in Cook County to clarify which features from other locales and eras should guide prevention efforts in the 1990s and beyond.

MATERIALS AND METHODS

Deaths handled by medical examiners and coroners are assigned one of five "manners of death": homicide, suicide, accident, natural, or undetermined. Cases that are ruled of an undetermined manner include those in which information is lacking to prove intentional injury or neglect, but in which there is evidence that precludes assigning the death a natural or accidental manner. The records of the Office of the Cook County Medical Examiner were reviewed to identify deaths of resident children, aged younger than 15 years, that were recorded from 1977 through 1982 with assigned manners of homicide or undetermined. Both manner of death categories were included to avoid an underestimation of the true incidence of violent death.

Twenty-six eligible records (5%) were not obtainable. Twelve cases were excluded from the analysis because of out-of-county residence. Twenty-five undetermined cases were excluded because available information indicated that they were almost certainly not violent deaths: 3 were medical/surgical mishaps, 4 were probable or suspected suicides,

5 were deaths that were most likely related to an underlying disease or condition, 2 were cases of sudden infant death syndrome, 4 were probable cases of sudden infant death syndrome, 3 were cases of probable aspiration, 1 was most likely to have been an unintentional injury, and 3 were fetal deaths before 6 months' gestation. This left 437 cases for analysis.

Uniform data were abstracted by one of the investigators (N.K.A.). Information was abstracted on demography, anatomy, and death circumstances; the information that related to death circumstances was based on available reports by police, medical examiner, and/or protective service investigators.

If a birth date was missing in the record, the best estimate of the year of age was entered based on the age listed on the death certificate. Latin and Oriental decedents were identified whenever possible, but familiarity with the records suggests that some of these may, at times, have been recorded as white. Data quality was assessed on a sample of study cases. For each case, 10 data items were reviewed. The overall transcription accuracy was 98%.

A census tract was assigned to each case based on the decedent's recorded address. As fewer than 3% of all records reviewed concerned noncounty residents, victims without recorded addresses (or with addresses not assignable to a census tract) were included in the analyses that did not require census data.

Data were analyzed (by D.A.M.) using the SAS computer program: frequency, χ^2 test, means, Scheffé test (to reduce the likelihood of a spurious identification of intergroup differences when a large number of comparisons was made), correlation, analysis of variance (general linear model for unbalanced data), and multiple linear regression.²⁰ Findings were considered to be significant for $P < .05$. Incidence rates were calculated as mean annual rates per 100 000 population in the 1980 census. For mapping and some analyses, area rates were calculated for community areas (standard groupings of census tracts) as the overall rate in incidence census tracts. This approach was used to avoid artificially high rates due to a high incidence in some individual tracts if only separate tracts were used for the analysis, and artificially low rates if the population in nonincidence

tracts were used to calculate area rates. For the analysis of social/demographic correlates of age-specific rates, multiple linear regression analysis was used, with incidence rates for victims aged younger than 1 year and aged 10 through 14 years dependent, and independent variables entered in a stepwise fashion ($P \leq .15$ for entry into and retention in the model). The census tract descriptor variables that were entered into the analyses were as follows: infant/toddler (age <3 years) population; teen (ages 10 through 19 years) population; child (ages 0 through 19 years) population; percentage of female-headed households; crowding (percentage in units with >1.01 persons per room); family median income; percentage of population nonwhite; homicide rate for 10- to 14-year-old children for the less than 1-year-old model; and homicide rate for the children aged younger than 1 year for the 10- to 14-year-old model.

Definitions

Tables in this report use terms that require definition. *Violent deaths* included both cases ruled as a homicide and those ruled as of an undetermined manner. As described above, the data excluded the undetermined deaths that were most likely to be due to causes other than assault, child abuse, or child neglect.

Based on the records reviewed, cases were assigned to one of nine *injury circumstances*: (1) blunt injury included trauma to the head and other body parts due to beatings, (2) gunshot, (3) arson (resulting in smoke inhalation), (4) fall, (5) burn, (6) neglect, (7) malnutrition, (8) strangulation and stabbing (excluding dismemberment), or (9) other. Head trauma was not separated from other types of beatings as originally intended, because most cases involved injuries both to the head and other body parts. Strangulations and stabbings were grouped together because of common situations: psychotic perpetrators, intruders, and desolate locales.

Perpetrators and Situations

Perpetrators were categorized as mother only, any father (father or stepfather only; mother and father or stepfather), other (acquaintance, including mother's boyfriend; stranger; unspecified), or unknown.

Fatal *injury situations*, the detailed sequence of events leading to death, were reconstructed when feasible from available information. These were grouped into clinically meaningful categories for tabulation and discussion. These categories often were not comparable (eg, argument and deserted site) due to variably available information.

Further details on the methods that we used can be obtained from the report on this

Fig 1.—Violent deaths of children in Cook County, Illinois, from 1977 through 1982. Study cases by age, gender, and race. Age in years indicates youngest age in category (eg, 0 is <12 months, 1 is 12 through 23 months, etc.).

study to the US Department of Health and Human Services, Washington, DC.²¹

RESULTS Overview of Cases

The study included 437 cases: 230 homicides, 206 of undetermined manner and 1 unclassified. The annual number of cases ranged from 59 (1977) to 88 (1980). There were more victims aged younger than 5 years than victims aged 5 years or older in winter (January, November, and December, 33% vs 16.5%) and more victims aged 5 years or older than victims aged younger than 5 years in summer (June, July, and August, 36.5% vs 16%, $P < .01$).

Sixty-one percent of victims were male, with males substantially outnumbering females after the age of 1 year. Approximately one third of victims were younger than 1 year, and almost half were younger than 2 years. The age distribution was U shaped. Black children were overrepresented: 70% of cases vs 34% of children younger than 15 years in Cook County in 1980 (D.

Injury Circumstance	No. (%)
Blunt injury	147 (34)
Gunshot	72 (16.5)
Arson	46 (10.5)

*Violent deaths include homicide and undetermined deaths. Mean annual rates per 100 000 population (<1 year, live births), 1980 census

ents were the predominant perpetrators among victims under age 5 years, in contrast to a predominance of others for children 5 years of age or older ($P<.001$). Among the third of cases with parent perpetrators, fathers were involved in more than half.

Homicide vs Undetermined Cases

Several analyses were done to compare cases of homicide and undetermined manner. Perpetrator distributions differed ($P<.001$ for eight perpetrator categories). Sex distributions by age were not significantly different. When mean ages were compared for homicide and undetermined cases within each circumstance category, these differed only for blunt injury (mean \pm SD: homicide, 2.8 ± 3.7 years vs undetermined manner, 1.2 ± 1.8 years; $P<.01$). In an analysis of variance with age dependent, injury circumstance contributed to the model ($P=.001$), but manner did not ($P=.82$), and there was no significant interaction between manner and injury circumstance ($P=.87$). As these analyses did

not seriously challenge the clinically motivated inclusion of both manners in the study, for the remainder of the report, "violent death" is used to include both homicide and undetermined cases.

Age and Injury Circumstances

The relationship between age and injury circumstance was demonstrated in the analysis described above. In addition, the victim mean age varied substantially for the different injury circumstances. In a pairwise comparison of mean ages for the nine injury circumstances using Scheffé's test, circumstance pairs that did not differ in mean age were considered to be clustered. This analysis revealed a "younger" cluster of circumstances, ie, blunt injury, arson, fall, burn, and neglect/malnutrition, and an "older" one, ie, gunshot, hit-and-run, and strangulation/stabbing. Gunshot deaths accounted for 49% of homicides among 10- through 14-year-old victims (age 10 years: 0%; age 11 years: 50%; age 12 years: 44%; age 13 years: 55%; and age 14 years: 56%).

Epidemiology: Geographic and Demographic Distribution of Homicide Cases

Mean annual age-, race-, and sex-specific rates per 100 000 population for homicide, undetermined manner, and all violent deaths were calculated for Cook County as a whole and for the city of Chicago (Table 3). Rates for the undetermined deaths exceeded those for the deaths that were ruled as homicides through age 4 years. The violent death rates showed a U-shaped distribution with respect to age.

There were large differences in death rates for age subgroups within the standard vital statistics age groupings. For example, Chicago violent death rates were 19.77 for the ages of 1 and 2 years, 6.35 for the ages of 3 and 4 years, 1.62 for the ages of 10 and 11 years, and 9.18 for the ages 12 through 14 years.

Male violent death rates exceeded female rates in most subgroups, and did so uniformly for victims aged older than 4 years. Violent death rates for Chicago were double or more than double those for the county as a whole. Rates for blacks exceeded those for whites, both in Chicago and in the county as a whole. The ratio of black to white homicide rates ranged from a low of 1.0 (for 10- and 11-year-old boys in Chicago) to a high of 10.4 (for 3- and 4-year-old girls in Chicago), with values between 2 and 5.5 for most subgroups.

All the violent deaths were confined to 259 census tracts; 22% of the 1232 census tracts with population in Cook County in 1980. Thus, the great majority of tracts had no violent deaths in the study age ranges. Tract-specific rate ranges varied by age: 0 through 2780 for age less than 1 year, 0 through 930 for the ages of 1 and 2 years, 0 through 480 for the ages of 3 and 4 years, 0 through 280 for the ages of 5 through 9 years, and 0 through 240 for the ages 10 through 14 years. The rate range in each age group was divided into two categories, high and very high, at the median rate for all incidence tracts. Mapping indicated that the areas with very high incidence rates for one age range were not always the same as those with comparably high rates for another age range, with the greatest discrepancies between the youngest and the oldest age groups (Figs 2 and 3: maps for <1 year and 10

through 14 years). Statistical analysis confirmed that the correlation between the younger than 1-year-old rates and the 10- through 14-year-old rates was weak ($r = .12$, $P = .053$).

Comparison of tracts with and without homicides showed that 53% of the 259 incidence tracts had 25% or more of their populations living below the poverty line, compared with 25% of the 893 nonincidence tracts. Multiple linear regression analyses produced extremely weak models relating social/demographic factors and homicide rates. For tract level analysis of infant homicide rates, only 11% of the variance in rates was explained (with child population, poverty, and teen homicide rates contributing to the model); for the 10-through 14-year-old rates, only 5% of the variance was explained (with infant rates, teen population, and crowding contributing). For the community area analyses, the models were even weaker. Thus, although an association between the homicide incidence and poverty was found, no strong demographic correlates of homicide rates in incidence tracts were identified.

Clinical Observations: Details of Fatal Injury Situations

Available information on the most frequent victim groups was used to gain a picture of the situations in which child homicides occur.

Child care at the time of death was known to have been provided by persons other than parents in 26 cases. The ages of these victims ranged from 21 days to 12 years (mean age, 32 months). When the gender of the caretaker was recorded, it was usually male (74%: 17/23). In almost half of the cases in which the perpetrator was identified as a baby-sitter (43%: 10/23) and in the majority of cases where the perpetrator was known to be a male baby-sitter (59%: 10/17), the mother's boyfriend was involved. Almost one third of identified baby-sitter perpetrators (30%: 7/23) were aged younger than 12 years, including several boys (3 of 7). Relatives of unspecified ages, most of them male, constituted one fourth of identified baby-sitter perpetrators (22%: 5/23).

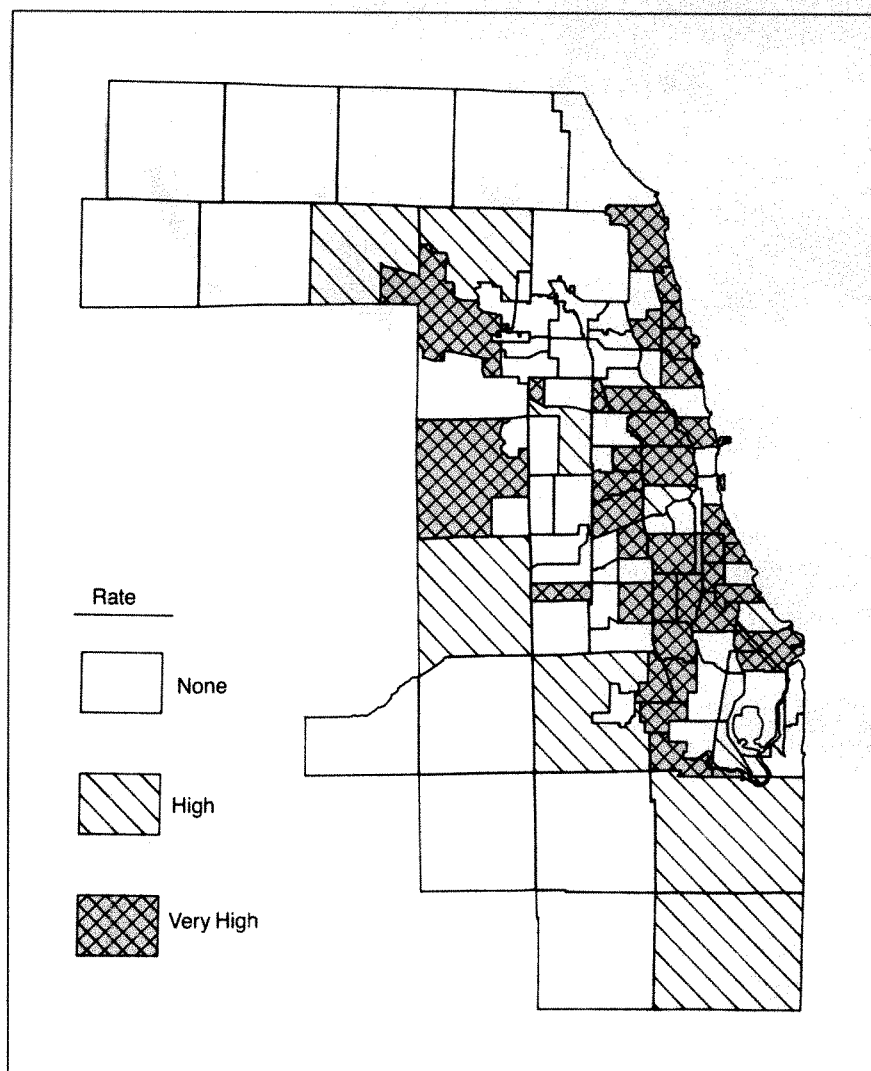

Fig 2. — Violent death distribution by community area: victims aged younger than 1 year.

Incidents that provoked the assault of young children were known in 12 instances: soiling/wetting ($n = 4$), crying ($n = 3$), eating/not eating ($n = 2$), "days and nights reversed" ($n = 1$), other (parents fought in one incident, and "punishment" another). When crying and other incidents were involved, the mean age was 16 months; when soiling/wetting and eating/not eating were involved, the mean age was 41 months.

The situations in which the gunshot deaths occurred are shown in Table 4. Eight (57%) of 14 of the "playing with/or showing a gun" deaths were ruled as of undetermined manner. The mean age varied substantially by situation.

The situations in which the 29 stabbing/strangulation deaths occurred are

shown in Table 5. For the majority (59% [17]), the situation was unknown, including 3 cases in which the bodies were found in dumpsters or garbage cans. When information was available, the situations were characterized by arguments with known persons (3 situations, including 1 concerning \$5), deserted sites (2 situations involved an abandoned building, and 1 involved railroad tracks), intruders ($n = 2$), and cults and related phenomena (eg, "message from God", $n = 3$; there were also 3 cases of dismemberment included in the "other/unknown" injury category that were associated with such phenomena). The age and sex of the victims varied with the situation. The youngest mean age was for cult killings (age, 3 years) and

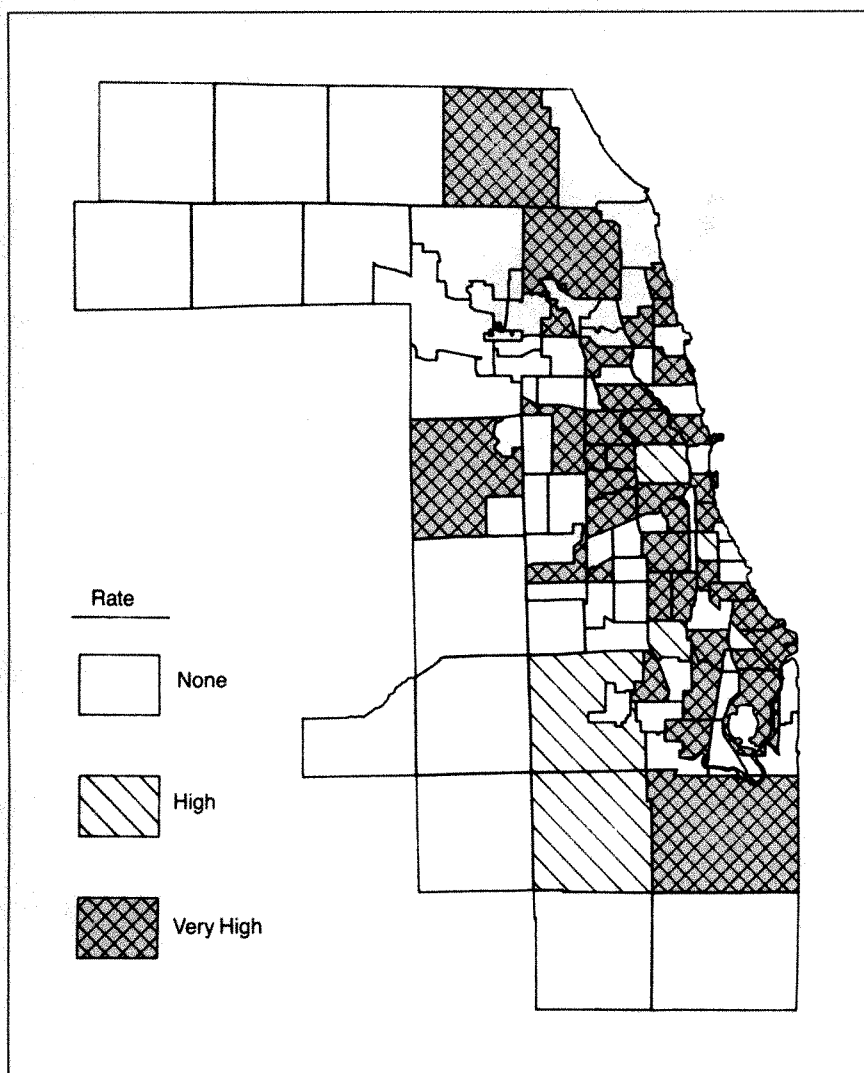

Fig 3.—Violent death distribution by community area: victims aged 10 through 14 years.

the oldest (age range, 12 through 14.8 years) for rapes, deserted sites, and arguments with known persons.

COMMENT Methodologic Considerations

The current report is based on one of the largest and most detailed child homicide data sets thus far studied, derived from death certificates, autopsy reports, and medical examiner records. This is one of several types of data that have been used to obtain information concerning child homicides. Each type of data has advantages and disadvantages.^{22,23} Protective services data are generally detailed, but exclude deaths in which the perpetrators are noncare-takers. These data exclude most older

child victims and younger children who die due to an assault by a stranger. Federal Bureau of Investigation and related data include only cases that involve police, ie, a variable subset of all suspicious child deaths. Vital data depend on the accuracy of the death certificates, which, in turn, depends on the quality of forensic investigation. Many jurisdictions have inconsistent access to trained forensic pathologists, whose child death investigations have set current standards.²⁴

The inclusion of undetermined cases in this study resulted in violent death rates that were virtually *double* the official rates in the younger age groups. It is likely that these higher rates are more nearly correct than the official rates.

Table 4.—Violent Death in Cook County, Illinois, From 1977 Through 1982: Gunshot Deaths: Relationship of Age to Injury Situation

Situation	No. of Deaths	Mean Age, y
Friend/acquaintance	14	13.2
Playing with or showing gun	14	9.8
Gang related	8	12.9
With parent suicide/homicide	7	2.5
Bystanding during gunfire	7	6.9
Associated with other crime	3	14.0
Other ¹	5	9.8
Unknown	14	12.7
All	72	10.5

The higher rates indicate that violent death, particularly in early childhood, is a problem of even greater scope than previous studies (of homicide only) have indicated.^{1,2,4} Some violent deaths, particularly in infancy, are not reported as homicides.^{25,26} Some of these are, usually appropriately, recorded as deaths of undetermined manner. Overestimation of homicide incidence due to data that include undetermined cases can be minimized by exclusion of cases that are unlikely to be violent based on available information, as in this study.

Study Findings

The present study extends our understanding of child homicide. Its results confirm findings of studies that have been done in other areas and locales, and supply needed details concerning age-specific incidence patterns. Findings that confirm the results of other studies include the existence of "younger" and "older" patterns of fatal injury,^{8,5-7,9,12,13,15,16,18} overrepresentation of male^{8,6,7,9,12,13,15,16} and black^{5-7,9,12,13,15} victims (particularly after infancy), association of homicide with urban residence and poverty,^{5,7,13,14-16,18,19} and the role of males as perpetrators.^{9,10,16} These commonalities, along with the type of data used and the fact that the calculated Cook County homicide manner death rates are comparable with 1983 US rates,^{21,27} suggest that the more detailed findings of the present study probably have good

generalizability.

Several of the details concern the role of rapid developmental changes during early childhood and adolescence in violent death incidence patterns. These reinforce the notion that violent death patterns in childhood are tightly tied to victim vulnerabilities related to biopsychosocial development,^{7,28} for which age is taken as a proxy. Seasonal patterns of violent death vary with victim age: winter is more dangerous for young children (who get beaten) and summer for older children (who get shot). Analyses using narrow age groupings revealed threefold to fivefold differences in incidence rates in subgroups within standard age groupings. These indicate that standard reporting practices with narrow age ranges must be added to current agendas for improved comparability of data sets.²⁹⁻³²

Age-specific patterns were found not only across but also within injury circumstances. For example, gunshot deaths rose abruptly at the age of 11 years, consistent with earlier analyses.²⁸ The youngest gunshot victims died in association with parental death, and the oldest gunshot victims died in association with peer interactions or crimes.

The study provides not only information but also questions concerning the risks that children face in their commu-

nities. Children of different ages were found to be most endangered in different areas. Census variables did not explain the variation in age-specific death rates across incidence tracts, although such variables account for much of the geographic variation in child abuse incidence.³⁴ Several factors probably contribute to this discrepancy. First, child abuse is more prevalent than child homicide; thus, it involves a much wider range of rates, ie, a more favorable statistical situation for finding a relationship to independent variables. Second, the multivariate analyses in this report are confined to incidence tracts; inclusion of non-incidence tracts would presumably confirm that homicide is closely tied to poverty, as in the bivariate analysis presented. Third, the choice of independent variables may affect results. Finally, there are systematic distortions in abuse statistics that exaggerate the relationship between abuse and poverty.³⁵ Future research will need to address these issues to clarify "the community factor" in child homicide risk.

Implications for Prevention

The consistency between the results of this large, contemporary, and detailed study and previous work suggests that the time has come to move beyond descriptive studies to preven-

tion trials. Observed age-related patterns of violent death suggest specific prevention approaches.

The deaths of very young children were, overwhelmingly, related to neglect or maltreatment by parents and other supervisors. Often, death resulted from violent attempts to deal with difficult but common behaviors of infants and toddlers. In such trying circumstances, the boys, girls, men, and women who provide child care require more or less automatic behavioral repertoires for dealing with their charges: it is difficult to think of options when one is violently angry. Means are therefore needed to provide future child caregivers with this kind of automatic behavioral repertoire. Perhaps doll and role playing, beginning in kindergarten, would protect future children when the kindergartners themselves become child caregivers, often sooner rather than later. Evidence that males are contributing increasingly to serious child maltreatment³⁶ emphasizes the need for boys, as well as girls, to learn to care for infants and toddlers.

The deaths of both male and female preadolescents and adolescents often occurred in situations in which the youngsters apparently failed to appreciate their danger and/or were unable to escape from it. This indicates a need for self-protection skills for boys, as well as girls, although our society generally offers such skills mainly to girls. Means must be found to teach such skills, probably beginning very early in life.

Although educational interventions with potential victims and perpetrators seem to be necessary, it is probably hazardous to rely entirely on such approaches.²⁸ Another prevention goal must be for communities to complement the child care provided by families, as families complement the education, transportation, and recreation that communities offer. The community role should include efforts to ensure young people safe passage through society. Gun control, with its promise of reduced contact by children with the second most common means of child homicide, is a possible starting point.

CONCLUSIONS

The study findings lead to the following conclusions:

1. Separate strategies are needed to protect the two groups at highest risk for violent death: black children aged younger than 3 years and aged older than 11 years in poor urban areas.

2. Standard homicide- and child abuse-reporting practices should include narrow age groupings in childhood and adolescence.

3. Age-related patterns of violent death must be considered in the planning of prevention trials. Enough is known to embark on this difficult enterprise.

4. Research is needed to clarify why children of different ages are at differing risks in different communities.

Firearm Ownership Among Nonurban Adolescents

Laura S. Sadowski, MD, MPH; Robert B. Cairns, PhD; Jo Anne Earp, ScD

• **Firearm injury is the second leading cause of death among teenagers. In this study we examined firearm acquisition and ownership in a biracial cohort of 664 teenagers (313 male and 351 female). Ownership was prevalent among male adolescents (48%) and rare among female adolescents (4%). Among these suburban and rural teenagers, the ownership rate was highest for white male adolescents (56%). Handgun ownership was more frequent among male school dropouts (22%) than enrollees (7%). The first firearm was typically acquired by late childhood or early adolescence (median age, 12.5 years). An adult male family member (eg, father, grandfather, uncle) was the primary source. The prevalence, developmental timing, and sociodemographic correlates of firearm acquisition should be useful for informing preventive clinical practice and interventions.**

(AJDC. 1989;143:1410-1413)

Firearm-related injuries are the second leading cause of death among 15- to 19-year-olds in the United States.¹ Firearms are involved in the majority of suicides and homicides among 15- to 19-year-olds and the mortality rate for unintentional or "accidental" firearm deaths is highest for this age group.² Morbidity data for firearm-related injuries are less available. Estimates of non-fatal firearm injuries are that for every firearm fatality there are at least five nonfatal injuries.³

An association between firearm availability and firearm-related deaths has

been suggested by ecological studies.^{4,5} In the United States, rates of firearm fatalities increase as rates of firearm ownership increase⁴ and parallel the number of new firearms available for sale.⁵ Studies of individuals have looked primarily at firearm availability among population subgroups, particularly gunshot victims in whom most deaths occurred in the residence where the firearm was kept.^{6,7}

Few studies have looked at firearm availability among adolescents despite the dramatic increase in the rates of firearm-related deaths in the 15- to 19-year-old age group.¹ In Baltimore, Md, a survey of high school students found that almost half the male adolescents carried a handgun and 37% said their parents kept a handgun at home.⁸ In another study, the availability of firearms within the home was higher for adolescents who committed suicide than for adolescents who attempted suicide and failed.⁹

Only modest information is available about the conditions surrounding firearm injury among teenagers, including the key issues of firearm availability and firearm ownership. We report on the behavioral and demographic characteristics of teenagers who own firearms, how and why they came to own them, and the firearm-related injuries they have experienced.

METHODS Cohort

This study was done in the context of a longitudinal research program that tracked a representative sample annually from childhood to early adulthood. The cohort was assembled in 1981 to study social development; its members have been interviewed annually. All fourth and seventh grade public school enrollees in two biracial school districts in a southeastern state were eligible; 70% of the children and their parents agreed to participate in the original study. Nonparticipants were similar to participants in age, sex, race, and school performance. One of the school districts is classified by the US census as

rural and the other suburban. Agriculture, small businesses, and textile and furniture manufacturing provided the predominant economic base in these districts.

Our sample of 664 teenagers represented more than 95% of the original 1981 cohort. Of the 32 teenagers (4.5%) not included, 5 had died and 8 did not give permission to participate; the interview tape for 1 teenager was inaudible, and for the remaining 18 teenagers, the interviewers felt that the conditions were inappropriate for sensitive questioning (eg, court house, history of avoiding interviewers, recent return from drug rehabilitation programs). The 27 living subjects not included were similar in age and socioeconomic status (SES) to other cohort members. However, among these 27 subjects, there were more male adolescents (59% vs 47%), whites (85% vs 75%), and school dropouts (67% vs 11%) than in the study sample.

Interviews

The 664 teenagers were interviewed between February 15, 1987, when the initial set of firearm ownership questions was added to the interview, and July 30, 1988. Firearm acquisition data were obtained from a subgroup of our sample, those teenagers interviewed after November 1, 1987 (ie, when these additional questions were included in the interview) who owned firearms ($n = 116$; 107 male and 9 female).

Thirty- to 60-minute, audiotaped, semi-structured, confidential interviews were conducted by two experienced interviewers. The interview location was usually a private office when the teenager was in school or in a private location at the teenager's job site or home when he or she had dropped out of school.

Variables and Analysis

The associations among firearm ownership and age, sex, race, recreational hunting, school enrollment, and SES were examined. Firearm ownership and acquisition status were determined using teenager self reports. Age, sex, and race were obtained from school records. Hunting was based on the teenagers' reports. School records and teenager reports determined school enrollment status and SES. Firearm mortality data were obtained from medical examiner re-

|| $P < .05$, χ^2 .¶Not significant, owners vs nonowners, using unpaired Student's t test.

Table 2.—Incidence of Firearm Ownership

Characteristic	P	Relationship More Likely If ...	Relative Risk (95% Confidence Interval)
Firearm ownership*			
Sex	<.001	Male	11.7 (5.5-24.8)
Race	.03	White	2.4 (1.1-3.9)
Hunting			
Past	<.001	Ever hunted	4.7 (2.0-10.5)
Current	<.001	Currently hunts	4.4 (2.0-9.0)

*Logistic regression model—age, school enrollment status, and socioeconomic status are not significant.

ports. Firearm morbidity data were obtained from unsolicited teenager reports.

The SES was measured using the Duncan Socioeconomic Index.¹⁰ This multidimensional scale was applied to the reported occupation of each adult living in the teenager's household. The highest SES score within each household was coded.

A firearm was defined as any gun from which a bullet or gunshot was discharged by gunpowder. Rifles, shotguns, and handguns (ie, a firearm held and fired typically with one hand) are subsumed by this definition. Pellet, BB, and air guns were excluded from the analysis. The number and type of all firearms were coded. Firearm ownership was defined as those firearms identified by the teenagers as belonging to them. Ownership of firearms was analyzed dichotomously, whether the teenager owned at least one firearm or owned no firearms. Handgun own-

ership was measured similarly. In addition, the following five self-reported variables measured how the firearm was acquired: the age at acquisition, the type of firearm acquired, the occasion of acquisition, the person who acquired the firearm, and the intended purpose for acquiring the firearm.

All 664 interviews were transcribed verbatim and coded by two research associates. Exclusive ownership of firearms was required; teenagers with firearms that were shared (ie, co-ownership) were not considered firearm owners ($n = 1$). A firearm was not considered a handgun unless it was explicitly described as a "pistol" or "revolver" or had a specific and complete handgun name (eg, "357 magnum"). Intercooder reliability for firearm ownership was .92, using a κ statistic. Test-retest reliability for firearm ownership for the 15 teenagers who were asked the study questions during their 1987

and 1988 interviews was .86, using a κ statistic.

The Statistical Analysis System was used for calculating the Mantel-Haenszel χ^2 test, unpaired Student's t tests, and Fisher's Exact Test statistics (two-tailed) for the bivariate analyses.¹¹ Stratification was used to control for possible confounders. Multivariate analyses for predicting the incidence of ownership of at least one firearm was performed using logistic regression.¹²

RESULTS

Sample Characteristics

The sample consisted of 313 male adolescents (47%) and 351 female adolescents (53%). The mean age (\pm SD) was 17.4 ± 1.7 years (range, 14 to 20 years of age). Seventy-five percent of the adolescents were white and 25% were black; 22% of the population in the counties of the two school districts was black. Eleven percent (69/619) of the teenagers 16 years of age or older had dropped out of school. The mean SES score for our sample was 31.3, slightly lower than the national average of 34.5.¹⁰

Firearm Ownership

In our sample, 162 teenagers owned 351 firearms. The rate of firearm ownership was 12 times higher among male than female adolescents (149 [48%] of 313 vs 13 [4%] of 351) ($\chi^2 = 172.9$, $P < .001$).

Table 1 summarizes firearm ownership. Among male adolescents, whites had a higher rate of firearm ownership than blacks (56% vs 20%). School enrollment status, SES, and age, within the age ranges of this sample, were not associated with firearm ownership (Table 1).

Male adolescents who hunted owned firearms more often than male adolescents who had never hunted. Prior hunting experience was associated with gender (more male adolescents than female adolescents), race (more whites than blacks), and firearm ownership (more owners than nonowners). When controlling for hunting experience, the racial difference in firearm ownership remained ($\chi^2 = 5.1$, $P < .05$).

In a logistic regression model for firearm ownership, sex, hunting experience, and race were associated with ownership of at least one firearm and explained 46% of the variance observed

Cumulative incidence of firearm ownership among male adolescents

(Table 2). In this model, school enrollment status, SES, and age were not associated with ownership.

Handgun Ownership

The rate of ownership of handguns was nine times higher among male than female adolescents (28 [9%] of 313 vs 5 [1%] of 351) ($\chi^2 = 19.8$, $P < .001$). Male adolescents who dropped out of school were more than three times as likely to own a handgun as those in school (Table 1). Male adolescents who had hunted owned a handgun more often than male adolescents who had never hunted. Handgun ownership among male adolescents was associated with owning other types of firearms; of the 28 male adolescents who owned handguns, 22 (79%) also owned a rifle or shotgun.

Similar to the racial differences found among firearm owners, handgun ownership ($n = 28$) was $2\frac{1}{2}$ times greater among whites than blacks, although statistical significance was not achieved. As was the case with ownership of firearms, SES and age were not associated with ownership of handguns among male adolescents.

In a logistic regression model of the incidence of handgun ownership among male adolescents, only school enrollment status was associated with the ownership of at least one handgun. The relative risk for school dropouts owning a handgun was 3.5 times the risk for enrollees (range, 1.3 to 8.3; 95% confidence interval [CI]).

Ownership Among Female Adolescents

Firearm ownership was rare among female adolescents (4%). Five owned a handgun and 8 owned either a rifle or shotgun. Among the 13 female firearm

owners, handgun ownership and rifle/shotgun ownership were mutually exclusive (ie, no one who owned a handgun owned a rifle or shotgun and vice versa) (Fisher's Exact Test, $P < .001$). Race, SES, and school enrollment status were not associated with firearm ownership among female adolescents. Among all female adolescents, 23% had hunted at least once. As with male adolescents, hunting experience was associated with owning a firearm among female adolescents (Fisher's Exact Test, $P < .001$).

Firearm Acquisition

Information describing the acquisition of firearms was obtained from 107 male adolescents who owned 149 firearms. Among male adolescents, firearms were acquired as a gift by 74%. Firearms were directly purchased by 16% of the male adolescents and inherited by 8%. Fathers were the source of 38% of the firearms, and other male relatives (eg, grandfather, brother, uncle) were the source of 22% of the firearms. When teenagers did not purchase the firearm themselves, the source, when specified, was almost always another man (96%). The reported purpose for acquiring the firearm was predominantly recreation (91%), rather than protection (4%) or adding to a gun collection (2%). The first firearm was usually a shotgun (49%) or a rifle (44%) rather than a handgun (7%).

Among male owners, the mean and median age of acquiring their first firearm was 12.5 years (range, 12.0 to 13.0 years of age, 95% CI); 22% of these teenagers were 10 years of age at the time they first acquired a firearm (Figure). There were no differences found between the age of acquiring the first firearm and the sex, race, hunting experience, SES, or school enrollment status of the owner (Figure).

Firearm Injury

During the course of this longitudinal study, 100% of the original group of 696 teenagers were tracked for a 6-year-period. There were 6 deaths, 3 related to motor vehicle injuries, 1 a suicide from a narcotic overdose, and 2 related to firearms. One subject died after being interviewed. Five male adolescents were involved in serious firearm-related injuries, 4 as victims (3 white, 1

black) and 1 as the perpetrator (white). There were 3 fatal and 2 nonfatal firearm-related injuries. Except for the 1 self-inflicted injury, all of these shootings involved male relatives. There were no firearm injuries among the female adolescents.

COMMENT

Firearm ownership is surprisingly common among particular subgroups of teenagers in this cohort. The majority of the white male adolescents owned firearms, and ownership first occurred during early adolescence. A striking difference in ownership rates appears in comparisons between white male adolescents (56%) and other sex-race categories (20% for black male adolescents, 4% for white female adolescents, and 2% for black female adolescents). The differential participation rates among male and female adolescents in firearm recreational activities (eg, hunting) does not wholly explain the gender differences in ownership. The racial difference in firearm ownership in our cohort may be, in part, due to fewer older men living in the homes of black teenagers¹³ or fewer older black men owning firearms themselves, and, therefore, being less apt to give firearms to other family members. The racial difference in firearm ownership is not due to SES. A statistically significant racial difference in handgun ownership was not found. This may, however, reflect the relatively small number of handgun owners in our sample.

Most firearm owners in this cohort acquired their guns as gifts, usually by early adolescence, and virtually always from an older male family member. This pattern may reflect a value system within these teenagers' families that encourages firearm ownership among male members. The circumstances that surround firearm ownership (ie, the timing of the initial acquisition in early adolescence, older men giving to younger male adolescents, and involvement in hunting, a strongly gender-typed activity) suggest that at least for some male adolescents, ownership plays a normative role during their transition from childhood to maturity. In support of this interpretation, firearms are portrayed as sources of responsibility in the written media, appealing to young boys

(*Boy's Life*, September 1988;78).

Potential limits to the generalizability of these findings deserve comment. This sample of teenagers lived in predominantly rural and suburban locations. Studies of firearm ownership among teenagers in urban settings may show rates different from this study, particularly among black teenagers, the majority of whom reside in urban areas.¹⁴ In addition, the possible influence of regional differences needs to be kept in mind.

These firearm ownership rates rely on self-reported data. In our study the interviewer-teenager relationship developed within a 6-year period to the point where a strong rapport and trust had been created. Teenagers in this study seemed to perceive their responses to these queries as important and confidential. Even so, our firearm and handgun ownership rates are probably an underestimation due to our stringent definitions and coding rules. The 27 teenagers not included were from the subgroup most likely to own firearms (predominantly male, white, and school dropouts).

The vast majority of all firearm deaths occur among household members, relatives, and friends¹⁶; most of the unintentional firearm deaths are within the home.¹⁵ The health threat from firearms is due, in part, to their lethality. Firearm ownership implies access to firearms and a self-determined amount and type of use, although for some teenagers this may depend, in part, on parental supervision, rules, or customs regarding firearms and safety

precautions. The relationship between firearm injury and the availability, accessibility, and use of firearms needs to be investigated further in multiple settings. During the course of this longitudinal study we documented serious firearm injuries in proportions roughly equivalent to the overall rates of firearm ownership found among male vs female adolescents and whites vs blacks. Undoubtedly, there are additional nonfatal firearm injuries that we were unable to identify.

The sheer prevalence of firearm ownership among teenagers demands broader recognition. Moreover, the multiple functions served by such ownership in adolescence need to be better understood. In the light of the present information on ownership prevalence and injury, families would seem likely to benefit from better information on the health hazards and product safety of firearms.

The role of physicians in the prevention of firearm injury, through influencing firearm availability among their patients, is twofold, as educators and advocates. Taking a medical history can provide access to information regarding the availability of firearms among patients. Educating patients on the hazards of firearms in the home can be incorporated into the health maintenance component of office visits. Repetition, reinforcement, and the inclusion of family members in this educational process is important.

Our findings suggest that certain guidelines are needed for the clinical implementation of steps toward the pre-

vention of firearm injuries. Since the majority of these firearms are gifts and men are the primary firearm givers and users within the family, the inclusion and cooperation of male family members seems important. If these individuals are not accessible to the clinician, identifying and including other key family members who could, in turn, influence these male adolescents could be substituted. Including these key influential family members in the patient educational process seems particularly important when dealing with the following: (1) boys in preadolescence or early adolescence, (2) depressed or potentially suicidal patients, and (3) patients and their families during stressful times.

As patient advocates, physicians can individually and collectively support the development and implementation of effective injury prevention programs in the community through workshops, community forums, or public service announcements. Collective action by local and national health professional organizations, as well as local consumer groups, is essential to deal effectively with this health problem. The American Medical Association and the American Academy of Pediatrics are two organizations that have supported legislation aimed at controlling firearm availability and injury.^{16,17}

The empirical work was supported by grant 22303 from the National Institute of Child Health and Human Development, Bethesda, Md. We are indebted to Beverley D. Cairns, Tamara R. Flincham, Scott D. Gest, and Holly J. Neckerman for their dedicated support and hard work, which made this study possible.

Prophylaxis of Recurrent Acute Otitis Media and Middle-Ear Effusion

Comparison of Amoxicillin With Sulfamethoxazole and Trimethoprim

Nicola Principi, MD; Paola Marchisio, MD; Emilia Massironi, MD;
Rosa Maria Grasso, MD; Gianfranco Filiberti, MD

• We compared the efficacy of amoxicillin with that of the combination drug sulfamethoxazole and trimethoprim in reducing recurrences of acute otitis media (AOM) in a single-blind, randomized, placebo-controlled trial involving 96 children. Each of the children had had three or more episodes of AOM in the preceding 6 months, and 97% (93/96) of them still had unilateral or bilateral effusion at the beginning of the study. During the 6-month study period, 9 (27%) of 33 of the children in the amoxicillin group developed 9 episodes of AOM, 9 (27%) of 33 of the children in the sulfamethoxazole and trimethoprim group experienced 11 episodes of AOM, and 19 (63%) of 30 of the children in the placebo group developed 25 episodes. Young age and day-care attendance characterized children for whom prophylaxis was more efficacious. Overall persistence of middle-ear effusion was shorter in treated children only as a consequence of the reduced number of new episodes of AOM. (*AJDC*. 1989;143:1414-1418)

Acute otitis media (AOM) is one of the most common pediatric diseases, characterized by a tendency to recur, especially during the first few years of life.¹⁻³ Recurrences may be clinically important, both because of the morbidity of each acute illness and because of possible long-term sequelae, such as delay in language development and learning disabilities.⁴⁻⁷

Antimicrobial prophylaxis is one of the medical options recommended for the management of this disease.⁸⁻¹³ Several studies have demonstrated the efficacy of various antimicrobial agents, such as the beta-lactam antibiotics (pen-

icillin V, ampicillin, amoxicillin) and sulfonamides.¹⁴⁻²⁴ However, data are lacking on the comparative efficacy of different prophylactic regimens, both in preventing acute episodes and in modifying the outcome of persistent middle-ear effusion.

Our study compares the efficacy of prolonged administration of low-dosage amoxicillin with that of the combination drug sulfamethoxazole and trimethoprim in a group of otitis-prone children.

PATIENTS AND METHODS

The study was conducted between October 1986 and September 1988. Children between the ages of 9 months and 5 years who were attending the outpatient clinic of Pediatric Department IV of the University of Milan (Italy) were enrolled in the study. Each child had had three or more otoscopically and tympanometrically documented episodes of AOM in the preceding 6 months. The last episode occurred between 15 days and 2 months before enrollment. At admission into the study, patients were free of clinical and otoscopic findings of AOM. Excluded from the study were patients who had cleft palate, Down syndrome, immunodeficiency, or a history of allergic reactions to any of the drugs tested. Also excluded were patients who had undergone surgical placement of tympanostomy tubes. Written informed consent was obtained from both parents.

At entry into the study, each patient was assigned randomly to one of three study groups: (1) children receiving amoxicillin, 20 mg/kg per day; (2) children receiving the combination of sulfamethoxazole and trimethoprim, 12 mg/kg per day; and (3) children receiving placebo. Drugs were administered once daily at bedtime in syrup form; the placebo was similar in appearance to one of the active drugs. All of the patients were treated for 6 months.

Patients were examined at entry into the study and subsequently at intervals of 4 to 6 weeks. They also were examined whenever

they developed symptoms of upper respiratory tract illness or symptoms suggesting AOM. At each visit, an interval history was obtained, and a complete physical examination and a tympanometric testing were performed. Pneumatic otoscopy was carried out in each case by the same examiner (P.M.), using a standard otoscope (Welch Allyn model 20200). Tympanograms were obtained with an electroacoustic impedance bridge (Amplifon, model Amplaid 709). The diagnosis of AOM was based on the presence of any combination of fever, otalgia, and irritability and on the presence of hyperemia or opacity accompanied by fullness, bulging, or immobility of the tympanic membrane confirmed by a flat, type B curve. The diagnostic criteria for otitis media with effusion (OME) consisted of the presence of impaired mobility, opacification and either bulging or retraction of the tympanic membrane, associated with a flat tympanogram, and the absence of general or local signs and symptoms of acute infection. Whenever AOM was diagnosed, prophylaxis was discontinued and treatment with cefaclor, 50 mg/kg per day in three doses for 10 days, was prescribed. Bilateral involvement was counted as a single episode. After treatment, if acute signs had subsided, chemoprophylaxis with the original drug was resumed. If acute signs persisted, the study protocol called for tympanocentesis to be performed and another antimicrobial drug to be administered, based on the sensitivity of the isolated pathogen. Tympanocentesis was contemplated only for children with persistent findings of AOM, because of the invasiveness of the procedure and to avoid any possible influence on the course of middle-ear effusion. If another infectious disease requiring antibiotic treatment occurred, prophylaxis was stopped and the more appropriate treatment instituted. Following recovery, prophylaxis was reinstituted. A child was discharged from the study if he or she developed two episodes of AOM within a 2-month period.

At entry into the study, at completion of the third month, and at the end of the treat-

*In the comparison of amoxicillin vs placebo and sulfamethoxazole-trimethoprim vs placebo, $\chi^2 = 6.88$; $P < .01$. In the comparison of drug groups combined vs placebo, $\chi^2 = 9.85$; $P = .002$.

ment period, a blood sample was taken from each patient for determination of hematologic, renal, and hepatic factors to detect drug toxicity. Leukopenia was defined as a total white blood cell count of $4.0 \times 10^9/L$ or less, neutropenia as a polymorphonuclear neutrophilic leukocyte count of $1.5 \times 10^9/L$ or less, anemia as a drop in the hemoglobin level of 20 g/L, and thrombocytopenia as a platelet count of less than $150 \times 10^9/L$.

Compliance with the study regimen was encouraged by asking parents to affix a written reminder of the protocol to the refrigerator door. Parents also were asked to bring the medication bottles with them at follow-up visits, and compliance was evaluated on the basis of the amount of medication remaining in the bottle. Failure to administer three or

more doses was considered poor compliance.

The occurrence rate of AOM was calculated as episodes per patient-month during the study period. The finding of OME in the same ear on two consecutive examinations was considered indicative of the persistence of OME in this ear during the intervening period. The same criterion was adopted for ears without OME. When OME was present on one examination and absent on the next, or vice versa, effusion was considered to have been present during half of the interval, that is, 2 to 3 weeks (in case of fractions, the value in weeks of effusion was rounded to the nearest unit).

All statistical tests were two-sided. Proportions were compared using the χ^2 test with Yates' correction for fourfold tables,

unless the sample was too small ($N = 33$), in which case Fisher's Exact Test was used. Mean values were compared using the Student t test. A stepwise logistic regression analysis²⁵ was used to investigate whether, in addition to the method of treatment, age, sex, season at entry, or day-care attendance influenced outcome, and whether there were interactions between any of these latter subject characteristics and the method of treatment.

RESULTS

A total of 100 children entered the study. Thirty-four were assigned to the amoxicillin group, 33 to the sulfamethoxazole and trimethoprim group, and 33 to the placebo group. Table 1 shows pertinent characteristics of the children at entry into the study. No statistically significant differences in these characteristics were found between the three treatment groups. One child in the amoxicillin group and 3 in the placebo group did not return for follow-up visits and were therefore withdrawn from the study. The remaining 96 were evaluated fully. The entire period of prophylaxis was completed by all of the children in the amoxicillin group (198 of 198 child-months). Children in the sulfamethoxazole and trimethoprim group completed 196 (99%) of 198 of the child-months, prophylaxis having been arbitrarily discontinued after 5 months in 2 children. Children in the placebo group completed 175 (97%) of 180 of the child-months; 1 child was treated with amoxicillin after 2 months because two episodes of AOM developed within 6 weeks, and this patient was retained in the placebo group only for the purpose of analysis of data concerning AOM and not for OME. In 1 child, placebo was arbitrarily discontinued after 5 months.

Table 2 shows data on the occurrence of episodes of AOM in the three treatment groups. In the amoxicillin group, 9 of 33 children developed 11 episodes of AOM; in the sulfamethoxazole and trimethoprim group, 9 of 33 experienced 9 episodes; and in the placebo group, 19 of the 30 children developed 25 episodes (1 child had 3 episodes, and 4 children had 2 episodes each). These differences between the drug groups and the placebo group in the proportions of children who developed AOM were statistically significant ($P < .01$). In each group there was a substantial reduction in the rate of

occurrence of AOM compared with the 6-month period before treatment, during which time each child had at least 0.5 episode per child-month. Thus, the mean rate fell from 0.52 to 0.06 in the amoxicillin group, from 0.57 to 0.05 in the sulfamethoxazole and trimethoprim group, and from 0.52 to 0.14 in the placebo group. No child underwent tympanocentesis because all the cases of recurrent AOM resolved on treatment with cefaclor. Seven (64%) of 11 of the episodes in the amoxicillin group developed during the first 3 months of prophylaxis, compared with 4 (44%) of 9 in the sulfamethoxazole and trimethoprim group and 20 (80%) of 25 in the placebo group. Two episodes in the sulfamethoxazole and trimethoprim group developed in children in whom the drug had been discontinued arbitrarily.

Table 3 shows data on the occurrence of AOM in the various epidemiologic subgroups. Consistently across subgroups, the rate of occurrence of AOM was lower in children receiving either amoxicillin or sulfamethoxazole and trimethoprim than in children receiving

placebo, but the difference reached statistical significance only in certain of the subgroups. The stepwise logistic analysis demonstrated that no statistically significant interactions were present among any of the subject characteristics and the method of treatment. Of the subject characteristics other than method of treatment, only day-care attendance influenced outcome; children attending day care had statistically significantly better outcomes than children not attending.

Table 4 shows data on the season of occurrence of AOM in relation to the season at entry. Irrespective of the season at entry and treatment group, a substantial proportion of all episodes of AOM (40% overall) occurred between April and September. Overall, the mean number of episodes per child appeared independent of the period of entry.

By the end of the 6-month study period, the persistence of OME in each treatment group had declined: OME was present in 51.5% (14/33) of the amoxicillin-treated children (39.4%

[13/33] bilateral, 12.1% [4/33] unilateral); 48.4% (15/31) of the sulfamethoxazole and trimethoprim group (35.5% [11/31] bilateral, 12.9% [4/31] unilateral); and 58.6% (17/29) in the placebo group (44.8% [13/29] bilateral, 13.8% [4/29] unilateral). The differences are not statistically significant. Data on the duration of effusion are shown in Table 5. The total duration of effusion, evaluated as total number of patient-weeks with OME, as well as number of patient-weeks with bilateral OME, was statistically significantly shorter in children treated both with amoxicillin and with sulfamethoxazole and trimethoprim compared with those treated with placebo. However, when children with recurrent AOM are not considered but only children who did not develop AOM are taken into account, the difference in total duration of OME among the three groups is no longer significant.

There was no laboratory or clinical evidence of toxic side effects due to treatment with amoxicillin or sulfamethoxazole and trimethoprim; in particular, we did not find any patient with hematologic abnormalities. The compliance was good in 97% (32/33) of children treated with amoxicillin, in 94% (31/33) of those receiving sulfamethoxazole and trimethoprim, and in 97% (29/30) of children who received placebo.

COMMENT

In recent years, several studies have been performed to evaluate the efficacy of antimicrobial prophylaxis in preventing recurrences of AOM in otitis-prone children. In most of the studies, antimicrobials were prescribed during cold-weather months or concomitantly with upper respiratory tract infections.¹⁴⁻²⁴ However, it is well known that in otitis prone children, "AOM does occur, albeit with reduced frequency, during the summer" as well.¹³ We therefore decided to enroll in the study all the children

*The number represents the percentage of total patient-weeks with otitis media with effusion (OME) (in parentheses, the number of patient-weeks with OME/the total patient-weeks). AOM indicates acute otitis media.

†In the comparison of amoxicillin vs placebo, $P < .05$.

‡In the comparison of sulfamethoxazole-trimethoprim vs placebo, $P < .05$.

with three documented episodes of AOM during the preceding 6 months, independent of the season in which they came to our observation.

Previous studies used mostly sulfonamides and, in only a few patients, aminopenicillins as prophylactic drugs. On the other hand, it has been demonstrated that in most patients recurrences of AOM are caused by the same bacterial agents commonly found in middle-ear fluid during the first episode of AOM.²⁶⁻²⁸ Therefore, we deemed it reasonable to select for prophylaxis amoxicillin and sulfamethoxazole and trimethoprim, which are usually considered among the drugs of choice for treatment of AOM.²⁹⁻³¹

Our data indicate that amoxicillin and sulfamethoxazole and trimethoprim administered at bedtime in low dosage for 6 months are equally effective, and superior to placebo, in reducing the occurrence of AOM in otitis-prone children. While prophylaxis is certainly more effective than placebo, the relatively small number of children enrolled in the study does not allow us to draw firm conclusions concerning the apparent equivalence of the two prophylactic regimens. Our study has the power to detect a 45% difference between the two drugs: lower differences might be detected only studying hundreds of patients. However, if we divide our population into two age subgroups, efficacy is statistically significant only for sulfamethoxazole and trimethoprim treatment in children up to 2 years of age, even if amoxicillin in both subgroups and sulfamethoxazole and trimethoprim in older children reduces from two to three times the incidence of recurrences

if compared with placebo. Our data agree strongly with those published by Perrin et al¹⁵ and Varsano et al,²² emphasizing the importance of chemoprophylaxis in younger children, and suggest the hypothesis that chemoprophylaxis could be more efficacious in children characterized by one or more of the known risk factors for recurrent AOM. In this way we could also explain the finding that chemoprophylaxis is more effective in children attending a day-care center compared with those cared for at home. Younger age and day-care attendance have, in fact, been demonstrated to be among the most important risk factors for recurrent AOM.³²⁻³⁴ Conversely, season at entry into the study did not seem to play a significant role in the efficacy of prophylaxis; this seems to sustain the possibility that AOM can recur throughout the year and that, after identification of the otitis-prone child, prophylaxis should be started at once. Finally, it is difficult to interpret the fact that prophylaxis is more efficacious in girls.

Concerning the effect of antimicrobial prophylaxis on the persistence of OME, our data suggest that prophylaxis may reduce the cumulative duration of effusion by decreasing the number of new episodes of AOM, but it does not otherwise affect the natural course of OME. In this respect our data amplify those published by Liston et al,¹⁸ who reported that sulfonamide prophylaxis improved the tympanogram pattern in children with recurrent AOM, and by Schwartz et al,¹⁷ who reported reduced occurrence of both AOM and OME. Those studies, however, did not differentiate children who continued to have

recurrent AOM during the study period from those who remained free of AOM. Because effusion often persists for many weeks after an episode of AOM, especially in younger children,^{6,31} it seems reasonable to anticipate that children treated with antimicrobial prophylaxis, having fewer recurrences of AOM than placebo-treated children, would also have shorter cumulative duration of OME. When we evaluated only children without recurrences of AOM, we found that the overall durations of effusion did not differ significantly between the three treatment groups.

On the basis of the data presented in this article, it seems reasonable to recommend the administration of chemoprophylaxis to otitis-prone children, especially if they are younger than 2 years of age and attend a day-care center. On grounds of safety, amoxicillin can be considered the first-choice drug, particularly in areas like Italy, where the problem of β -lactamase-producing strains of *Haemophilus influenzae* and *Moraxella (Branhamella) catarrhalis* is still limited. The combination drug sulfamethoxazole and trimethoprim can be used in children with known allergy to β -lactam antimicrobials or in areas in which the incidence of amoxicillin or pathogens resistant to sulfonamides is increasing rapidly. Both drugs appeared to be well tolerated and safe. In particular, we did not experience any of the most troublesome adverse effects reported both with amoxicillin and with sulfamethoxazole and trimethoprim. The safety of sulfamethoxazole and trimethoprim given at low dosage has been reported in several studies on the prophylactic treatment of recurrent uri-

nary tract infections.^{35,36} Because new episodes of AOM continued to occur, especially in the placebo group, between April and September, we suggest that the duration of the chemopro-

phylaxis be a minimum of 6 months, irrespective of the season of the year in which it is instituted. Once-daily administration at bedtime was well accepted and afforded good compliance and may

be preferable to the twice-daily administration proposed by some authors.^{11,37}

Predictors of Trough Serum Gentamicin Concentrations in Neonates

Pam S. Keyes, RNC, CCRN; Carolyn K. Johnson, MD; Timothy D. Rawlins, MA

• Neonates admitted to an intensive care nursery frequently receive gentamicin sulfate therapy. This study was undertaken to determine predictors of an elevated (≥ 2 mg/L) trough serum concentration of gentamicin sulfate (undesirable because of potential toxic effects). A total of 140 infants with birth weight of 496 to 4545 g and gestational age of 23 to 42 weeks who received gentamicin in the first days of life were studied prospectively. The trough serum concentration of gentamicin was not significantly affected by concurrent use of dopamine hydrochloride, indomethacin, furosemide, or umbilical artery catheters. Of 11 infants weighing between 1000 and 1500 g on an 18-hour dosing interval, 55% had trough serum gentamicin concentration of 2 mg/L or more. Use of the recommended 24-hour dosing interval for infants weighing less than 1000 g and an 18-hour schedule for preterm infants weighing more than 1000 g resulted in a significant number of elevated trough serum gentamicin concentrations in the latter. A dosing interval of 24 hours for infants less than 1500 g and 18 hours in infants between 1500 and 3250 g is suggested.

(AJDC. 1989;143:1419-1423)

Gentamicin sulfate, an aminoglycoside, is used frequently in neonates to treat suspected or proved infections caused by gram-negative organisms.¹ The use of aminoglycosides also improves the antibacterial activity of penicillins against group B streptococci, *Listeria* organisms, staphylococci, and other bacterial pathogens of newborn

infants.² A peak serum concentration of 4 mg/L has been suggested as a minimum inhibitory concentration for most susceptible gram-negative organisms.¹⁻⁶ Hence, a peak serum concentration of 4 to 8 mg/L is considered to be in the therapeutic range,¹ and a concentration more than 10 mg/L is considered toxic.³

It is recommended that the trough serum concentration, determined before gentamicin administration, be maintained at less than 2 mg/L to prevent toxic effects.^{1-5,7-9} Information is scarce concerning use of the trough concentration to assess toxicity. Assael et al⁶ used 1 mg/L as an indication of possible gentamicin accumulation. Matzke et al⁸ set a lower limit of 0.5 mg/L and stated that this was an arbitrary value to prevent subtherapeutic dosing. Although disagreement exists about whether the peak or trough concentration is a better indicator of toxicity, Jolley et al¹⁰ stated that the trough serum concentration rather than the peak concentration offers a more discrete indication of acute toxicity as the trough serum concentration correlates more closely with tissue accumulation.

In adults, gentamicin has the potential of causing ototoxicity and nephrotoxicity. This cause of toxicity remains a controversial issue in neonates due to the limited number of studies available. Nephrotoxicity usually starts with damage to the proximal renal tubules, resulting in acute tubular necrosis characterized by increased excretion of β_2 -microglobulin, proteinuria, and urinary tubular casts. Later increases in serum creatinine and urea nitrogen concentrations occur.¹¹ However, the injury can usually be reversed with discontinuation of the drug.

Ototoxicity can result in loss of equilibrium, loss of hearing, or both. Early hearing damage can potentially be reversed if the gentamicin treatment is

discontinued; however, recovery of the vestibular apparatus is less likely.²

Because of potential toxic effects, the serum gentamicin concentration should be monitored and the dose adjusted to maintain a trough concentration of less than 2 mg/L and a peak concentration between 4 and 8 mg/L.¹ Variability in serum drug concentration is not unexpected in patients in the neonatal intensive care unit due to inconsistency in drug clearance, associated illnesses, complications, and the effects of other drug therapies received by these infants.

The recommended dose of gentamicin for full-term infants is 2.5 mg/kg every 12 hours.^{1,6} Pharmacologic studies of Szefer et al⁵ and Zarowitz et al¹² have shown that a large number of preterm infants have a high trough serum concentration unless the dosing interval is lengthened.

The protocol for gentamicin administration in our nursery provides for a longer dosing interval for very low-birth-weight infants (ie, those weighing <1500 g). However, our observation of an undesirable number of elevated trough concentrations that required a further modification of the standard protocol schedule prompted us to undertake this prospective investigation.

The objectives of this study were (1) to evaluate the current protocol in minimizing toxic serum drug concentration while maintaining an appropriate therapeutic concentration; (2) to determine predictors (eg, gestational age and birth weight) for peak and trough serum gentamicin concentrations; and (3) to determine the influence of furosemide, dopamine hydrochloride, and indomethacin, which are often used concurrently with gentamicin sulfate in the first days of life of the premature infant, on the occurrence of an elevated trough concentration.

PATIENTS AND METHODS

Patients

The study subjects consisted of all infants admitted to the Special Care Nurseries, Hospital Corporation of America Wesley Medical Center, Wichita, Kan, who received intravenously administered gentamicin within the first hours of life and had peak and trough serum levels determined. Infants with confirmed congenital renal anomalies were excluded from the study. Data were collected from November 1, 1987, to January 13, 1988. The protocol was approved by the Institutional Review Board at Hospital Corporation of America Wesley Medical Center.

Study Protocol

The protocol for gentamicin sulfate administration during the study period was a dose of 2.5 mg/kg with a dosing interval of 24 hours for infants weighing less than 1000 g. Infants weighing between 1000 and 1500 g were prescribed a dosing interval of 18 or 24 hours; infants weighing more than 1500 g were prescribed an interval of 12 or 18 hours, with the attending physician making the decision as to which interval was used. Birth weights in the three groups ranged from 496 to 1282 g, 948 to 4545 g, and 1494 to 4355 g for 24-, 18-, and 12-hour dose intervals, respectively.

Gentamicin sulfate was administered through a peripheral vein. It was mixed in a dextrose-water solution (the same concentration as the infant's intravenous fluid) and infused through extension tubing for a period of 1 hour using an infusion pump.

Trough serum samples were collected 15 minutes before gentamicin administration, and peak serum samples were collected 1 hour after the infusion was complete. Serum samples were collected routinely with the fourth dose; however, some were collected with the second to fifth dose (mean = 3.8) as ordered by the staff physicians. Samples were collected from umbilical artery catheters, from radial arterial catheters, or by heel stick.

The serum gentamicin concentration was determined by fluorescence polarization immunoassay technology and competitive binding immunoassay method. The CV was 5% at 2.0 mg/L and 3.8% at 5.06 mg/L.

Information gathered from the patient's chart consisted of birth date, time, and weight, and gestational age (using the modified Dubowitz scale); gentamicin dose and dosing interval; date and time of blood sample collection; urine output for the 24-hour period before sample collection and most recent serum creatinine concentration; the presence of an umbilical artery catheter; and concurrent treatment with furosemide, dopamine, and/or indomethacin.

Statistical Analysis

Data were analyzed by factorial one-way analysis of variance (ANOVA) and multiple regression. These two methods yield similar results, are based on the same general linear model, and follow essentially the same assumptions.¹⁸ Analysis of variance was used to demonstrate mean differences first in trough concentrations and second in peak concentrations between the three treatment intervals (a larger sample size would allow a more robust test of group differences). Multiple regression analysis was performed to predict mean trough or peak serum concentration (criterion measure) based on combinations of birth weight, treatment interval, age in hours when measured, dose number, total amount of gentamicin given, creatinine level, urine output, umbilical artery catheter, and administration of furosemide, dopamine, or indomethacin (predictor variables).

Multiple regression analysis followed two steps: first, commonality analysis was used to determine which independent variables were adequate predictors of gentamicin concentration, and second, predictions were made based on regression equations obtained by a forward and backward stepwise solution using a strict F test to enter and remove variables. This procedure resulted in a subset of variables that maximally correlated with trough gentamicin concentration, maximizing accuracy of prediction and raising the subjects to variables ratio beyond the 10:1 ratio needed.

Furthermore, we were interested in the probability that infants with given characteristics (eg, birth weight, creatinine level, urine output, treatment interval) would have a toxic trough gentamicin concentration. Several approaches to selecting a subset of predictors that maximize the probability of this occurrence were possible. Stepwise logistic regression can be used with discrete or mixed discrete-continuous predictors, although multiple regression can also be used if discrete variables are recoded as vectors. In this study, we "dummy-coded"^{14,15} discrete variables to create vectors such that, in any given vector, membership in a given group or category was assigned a variable of 1, while nonmembership was assigned 0. Coding for treatment groups required two ($k-1$) vectors—vector 1, the 18-hour dose interval, and vector 2, the 12-hour dose interval. The vector 1 and 2 variables for the 12-hour dose group were 0 and 1, respectively; for the 18-hour dose group, 1 and 0, respectively; and for the 24-hour dose group, both were 0.

The principle problem with stepwise multiple regression in predictive models is that different orders of entry and removal of predictors into the regression equation may produce notable differences in the relation of each predictor to the criterion measure.

Variable selection becomes less problematic when preceded by commonality analysis, which determines the unique variance of each predictor (or set of predictors) with the criterion measure. Unique variance is the variance associated with a predictor when it is entered into the equation last; in other words, it is the squared, semipartial correlation between the criterion and predictor variable of interest after the partialing of all the predictors from it. Commonality analysis explains the relative predictive power of the regressor variables and determines their usefulness as predictors, guiding subsequent multiple regression analysis.¹⁵

The multiple regression equation has the following form: $Y' = a + b_1X_1 + b_2X_2 + \dots + b_pX_p$, where X_1, \dots, X_p are the predictors used to provide a least-squares estimate of the criterion measure (Y'). The variable Y' is in fact an estimate of the mean Y score of all individuals with a given combination of X_1, X_2, \dots, X_p scores.^{14,15} Since Y' is a mean, we can calculate the probability that an individual's predicted score does not fall below some specified cutoff score (Y^*) by converting Y to a z score: $(z = Y - Y')/s_{y|x}$, where $s_{y|x}$ is the SE of estimate of the regression equation. In other words, the resulting z score expresses the relation of the SE of estimate to the cutoff and predicted gentamicin concentration (ie, its probability of falling below the cutoff). Calculating probabilities in this fashion requires that the variables be multivariate normal.

Calculating the "best guess" estimate of trough serum gentamicin concentration from the regression equation $Y' = 1.85 - 0.000486$ (grams of birth weight) $+ 0.779$ (18-hour interval) $+ 1.669$ (12-hour interval) is as follows for a 2000-g infant on an 18-hour treatment schedule: $Y' = 1.85 - 0.000486(2000) + 0.779$ (coded 1) $+ 1.669$ (coded 0), thus $Y' = 1.657$ (nontoxic concentration).

If we assume that 2.0 mg/L is the cutoff for a toxic trough, the resulting z score is $(2.0 - 1.657)/0.538 = 0.638$. Since a z score of 0.638 cuts off 0.2611 of the area under the gaussian curve with a mean of 2.0, the probability of toxicity for this infant is .2611.

RESULTS

Demographic characteristics of the infants grouped by gentamicin dosing interval (12, 18, and 24 hours) are shown in Tables 1 and 2.

Peak Gentamicin Concentration

All but six (96%) of the infants had a peak serum gentamicin concentration between 4 and 8 mg/L. Five of the six had a peak serum concentration below

Table 1.—Mean Gestational Age, Birth Weight, and Renal Function by Treatment Group*

Characteristic	Treatment Group		
	12-h Interval (n = 77)	18-h Interval (n = 49)	24-h Interval (n = 14)
Gestational age, wk	36.3 (30-42)	33.1 (27-43)	27.4 (23-29)
Birth weight, g	2685.2 (1444-4365)	1899.0 (948-4545)	926.8 (496-1188)
Postnatal age, h†	44.3 (16.5-163.8)	61.2 (36.8-255)	61.8 (48-75)
Total drug dose, mg‡	18.2 (1.2-31.5)	13.4 (3.9-33)	5.5 (2.5-9)
Hourly urine output, mL/kg	4.4 (0-9)	4.5 (.81-9)	4.5 (1.4-10)
Creatinine level, μ mol/L	180 (30-800)	160 (40-800)	90 (50-130)

†Age when trough serum samples were drawn.

‡Dose indicates the total amount of drug received when trough serum samples were drawn.

4.0 mg/L; these five infants were of higher birth weight in the 18-hour dose group (mean birth weight of 3148 g [range, 1937 to 4545 g], compared with mean birth weight of 1899 g [range, 948 to 4545 g] for the entire group). One infant had a toxic peak serum concentration; however, in reviewing the chart, the peak was determined too early (just after the infusion was completed). The ANOVA indicated no difference in the mean peak concentration between the treatment groups ($P = .0598$). Stepwise multiple regression indicated that the only predictor of peak gentamicin concentration was trough concentration, which accounted for 27.5% of the variance in peak concentration ($r = .524$, $R^2 = .275$).

Trough Gentamicin Concentration

Table 3 shows the prevalence of an elevated trough serum gentamicin concentration in the three study groups.

When the patients were divided by dose interval, ANOVA indicated significant differences in the mean trough concentration between the three groups ($P < .0001$). Post hoc analysis with Fisher's Exact Test of least significant difference indicated that the mean trough serum concentration for the 12-hour dose interval was significantly ($P = .01$) greater than either the 18- or 24-hour mean trough serum concentration.

Commonality analysis, using trough serum gentamicin concentration as the dependent variable, indicated that only three variables (birth weight, 12-hour interval, and 18-hour interval) contained sufficient variance to be used as predictors of trough serum concentration; together they accounted for 36.5%

Table 3.—Observed Frequency of Elevated Serum Gentamicin Trough Concentration for the 12-, 18-, and 24-Hour Treatment Intervals

Birth Weight Range, g	Dose Interval, h	N	Trough Concentration*	
			>2 mg/mL	<2 mg/mL
1494-4355	12	77	50 (65)	27 (35)
948-4545	18	49	19 (39)	30 (61)
496-1282	24	14	1 (7)	13 (93)
Total		140	70	70

*Percent of total is given in parentheses.

of the variance (Table 4). Gestational age was excluded from the analysis due to its correlation of .88 with birth weight.

Subsequent stepwise multiple regression resulted in a highly significant ($P < .0001$) regression equation ($r = .64$, $R^2 = .41$, SE of estimate = .538). The raw score formula for predicting gentamicin trough is $1.85 - 0.000486$ (grams of birth weight) + 0.779 (18-hour interval) + 1.669 (12-hour interval). Probability estimates of toxic vs nontoxic treatment outcomes from this equation are presented in the Figure.

As indicated by their small unique variances (Table 4), variables other than birth weight and treatment interval contributed little to the prediction of the trough concentration. There was no statistically significant relationship between urine output and elevated trough serum gentamicin concentration in our study infants whose hourly urine output varied from 0.71 to 7.29 mL/kg. Fifty-one patients had umbilical artery catheters placed as "high" catheters positioned between T-6 and T-10 (standard placement for our nursery). Our data showed a small but nonsignificant increase in trough concentration associ-

relate (ie, predict) an elevated trough serum gentamicin concentration.

COMMENT

Aminoglycosides are bactericidal and produce their antimicrobial effects by penetrating bacterial cell walls and becoming irreversibly bound to the 30s unit of ribosomes in the cytoplasm.³ At this site, they inhibit protein synthesis, which leads to a misreading of the genetic code and to cell death.^{2,3,9}

Aminoglycosides are all nearly identical in their absorption, distribution, and excretion. Aminoglycosides are lipophobic and minimally protein bound; therefore, they are distributed mainly in extracellular fluid.⁸ They are bound to kidney tissue and taken up and concentrated in the renal cortex,¹⁰ where they are slowly excreted from tissues (average gentamicin half-life is 112 hours from renal parenchyma compared with 2 to 3 hours from serum¹¹). The extent to which the drug accumulates seems to correlate with nephrotoxicity.¹¹ It is this potential for causing nephrotoxicity, as well as ototoxicity, that requires frequent monitoring of serum gentamicin concentration.

The recommended sampling time for peak serum concentration is 30 to 60 minutes after an intravenous infusion and 30 to 90 minutes after intramuscular injection.¹¹ This allows for ample distri-

bution of the drug to the tissues. Hindmarsh et al,¹ Mulhall et al,⁴ Szefer et al,⁵ and Zarowitz et al¹² used the level determined 1 hour after gentamicin administration as the peak concentration, and it has been the routine sampling time in our nursery.

Gentamicin clearance is decreased in renal failure, and the dosing interval schedule must be modified to avoid accumulation that may lead to toxicity. We had anticipated that urine output and creatinine level would serve as predictors of gentamicin concentration. However, their power to do so was low. An explanation for this may be that few infants were actually oliguric (<1 mL/kg per hour), and none was severely oliguric (<0.5 mL/kg per hour). The infant's creatinine level is slightly elevated at birth, probably reflecting the mother's plasma concentration,¹⁷ and declines after birth. Thus, an increase in the serum creatinine level during the first days of life (based on multiple determinations rather than a single determination as studied here) may be more predictive of an elevated trough serum gentamicin concentration.

Decreased renal blood flow has been considered a side effect of high umbilical artery catheter placement and, thus, could have an effect on the clearance of gentamicin. This placement seemed to have minimal effect on gentamicin

clearance in our group of infants, however.

Infants receiving gentamicin therapy, especially preterm infants, frequently receive other drugs that potentially influence gentamicin pharmacokinetics or the clearance of gentamicin through an effect on renal function. Therefore, we reviewed the use of furosemide, dopamine, and indomethacin with gentamicin to determine their effects on trough serum gentamicin concentration.

Indomethacin, a prostaglandin synthetase inhibitor, is commonly used for the pharmacologic closure of a patent ductus arteriosus in the first days of life. Side effects associated with the use of indomethacin include hyponatremia, a 60% decrease in urine flow rate, a 30% to 40% decrease in glomerular filtration rate, and a variable decrease in electrolyte excretion and renal blood flow.¹⁸ Indomethacin has also been found to prolong the half-life of gentamicin through its effect on the glomerular filtration rate.¹⁸

Dopamine, a naturally occurring catecholamine, has a positive cardiac inotropic action and causes selective renal vasodilation in humans and animals.¹⁹ It has been used increasingly in recent years to treat low cardiac output and hypotension in premature infants. Dopamine also has been claimed to blunt the renal tubular side effects of indomethacin¹⁷ and, in low doses (2 to 7 μ g/kg per minute), increases renal blood flow.

Furosemide, a potent diuretic, promotes natriuresis and diuresis in premature infants. Its usage has been claimed to prevent the renal side effects of indomethacin.¹⁷

The use of these drugs with gentamicin could change the clearance of the antibiotic, either increasing it with the use of furosemide and dopamine or decreasing it with the use of indomethacin, and thus affect the measured serum concentration of gentamicin. However, no significant effect of these drugs on trough serum concentration was noted in our infants. The combination of the drugs received by some of the infants may have masked an effect of any one drug, but there were too few infants receiving more than one of the three drugs to test for this.

Our data confirm the association of trough serum concentration with dosing interval and birth weight. Similar associations have been found in other studies.^{1,4,6} This relationship appears to be independent of the other variables we studied.

We found that 58% of infants who weighed between 1000 and 1500 g had an elevated trough serum concentration on an 18-hour dosing schedule. We also noted a significant number of infants weighing between 2500 and 3250 g (Figure) who had an elevated trough serum concentration on the 12-hour dosing schedule. These results are somewhat different from those of Zarowitz et al,¹² who, in a prospective study, noted that on the third day of therapy, 21% of the infants between 28 and 34 weeks old on the 18-hour schedule and 41% of infants older than 34 weeks on a 12-hour schedule had trough serum concentrations higher than 2 mg/L.

To minimize the number of toxic trough serum concentrations while maintaining therapeutic peak concentrations, our data suggest the following modification of the dosing schedule during the first 4 days of life: for infants weighing 500 to 1500 g, a 24-hour dose interval, and for infants weighing 1500 to 2500 g, an 18-hour dose interval.

The most appropriate dose and interval for infants between 2500 and 3250 g is more problematic. We had 25 infants

in this group; 48% (12/25) had a toxic trough serum concentration and a therapeutic peak concentration. All of the 12 with an elevated trough concentration were on 12-hour dosing schedules, suggesting that this short dosing interval may not be optimal, even for these larger infants. Two of the remaining infants had a nontoxic trough concentration; however, their peak concentration was subtherapeutic. These two infants were on an 18-hour schedule; therefore, extending the interval may not be the satisfactory solution in these large infants. Wennberg and Goetzman¹⁹ recommend 3 mg/kg every 24 hours for infants weighing less than 2000 g and younger than 1 week. A dose of 3 mg/kg every 18 hours for newborns with birth weight between 2500 and 3250 g may provide a higher but nontoxic peak serum concentration, questionably more effective, and allow for a lower and less toxic trough concentration. However, we have not tested this hypothesis clinically.

Because so many infants receive prophylactic antibiotic therapy, it is important to minimize toxic effects; however, it is just as important not to treat infants inadequately if they have a life-threatening infection. The dose of 2.5 mg/kg every 12 hours seems to be satisfactory in term infants of greater than 3250-g birth weight, but may result in an unacceptably high number of toxic trough

serum concentrations in infants weighing between 2500 and 3250 g. Therefore, further studies are needed to determine optimal dosing in these infants. We have implemented the longer (24-hour) dosing interval to include infants weighing 1000 to 1500 g in our nursery and are collecting data to evaluate the prevalence of toxic trough or subtherapeutic peak concentrations on this protocol. Infants who weigh less than 1000 g continue to receive 24-hour dosing as previously described. The results of this study apply to newborns during their first days of life; infants who receive gentamicin beyond the first week of life may need a change in the dosing interval because of changing renal function during the first weeks of postnatal life. Indeed, a shorter dose interval (8 hours) has been recommended for term infants older than 7 days, based on this postnatal maturation of renal function. Our study did exclude infants who were still of very low birth weight at a postnatal age of older than 1 week. Further studies are needed to determine the changing pattern of gentamicin drug clearance in older preterm infants so that appropriate dose and dose-interval recommendations can be made.

This study was supported by Wesley Medical Research Institutes, Wichita, Kan.

Charlotte Schideler, PhD, provided technical assistance, the neonatal intensive care unit nurses assisted with the study, and Jackie Ackerman prepared the manuscript.

Morbidity and Mortality in Children With Pyogenic Liver Abscess

Victor M. Pineiro-Carrero, MD, Joel M. Andres, MD

• Review of our experience from 1975 to 1986 and a literature survey disclosed 109 children with pyogenic liver abscess. During this time, newer imaging techniques, especially ultrasonography and computed tomography, facilitated the prompt diagnosis of cystic lesions within the liver parenchyma. The incidence of pyogenic liver abscess at our institution (25 per 100 000 pediatric hospital admissions) was higher than previously reported. Since the majority of abscesses were located in the right lobe of the liver, patients were most effectively treated with percutaneous drainage of the abscess cavity. *Staphylococcus aureus* was the most common bacterial agent responsible for pyogenic liver abscess; however, anaerobic organisms were noted as a major group of pathogens and represented 27% of our patients. Furthermore, one patient was discovered to have multiple microabscesses of the liver associated with cat-scratch disease; pleomorphic gram-negative bacilli were not cultured. Among the 109 patients, the overall mortality of 15% was considerably better than that for children with PLA before 1975. The improved survival may be related to more prompt diagnosis of pyogenic liver abscess followed by evacuation of the liver abscess and antibiotic therapy.

(AJDC. 1989;143:1424-1427)

Pyogenic liver abscess (PLA) is a life-threatening disease in children that requires prompt diagnosis and therapy. Two extensive reviews in the pediatric literature are autopsy studies, which emphasize the high mortality for patients with this disorder.^{1,2} An incidence of 3 cases of PLA per 100 000 pediatric hospital admissions was reported³ for

years before 1977, with a mortality for these children of 36%. Recent reports in the adult literature describe a reduction in morbidity and mortality due to earlier diagnosis and improved therapeutic drainage procedures.^{4,5} Prompted by our experience involving three children with PLA during a 1-year period, we were interested in determining whether a similar reduction in morbidity and mortality could be determined for children.

PATIENTS AND METHODS

Eleven patients under 18 years of age were admitted to the University of Florida Shands Hospital, Gainesville, between January 1, 1975, and June 30, 1986, with the diagnosis of "liver abscess." Patients were included in this retrospective study if they met one or more of the following criteria: (1) percutaneous aspiration of purulent material from one or more intrahepatic cystic cavities, (2) demonstration of intrahepatic cavities by imaging techniques associated with positive blood cultures, and resolution of the symptoms after antimicrobial therapy, and (3) discovery of one or more liver abscesses at surgery or at autopsy.

Specific information was sought about initial symptoms, clinical signs, laboratory data including results of bacterial cultures, imaging techniques, open and closed PLA drainage procedures, antimicrobial therapy, and outcome. In addition, the number and location of liver abscesses and the presence of underlying diseases were noted.

RESULTS

The 11 patients with PLA identified since 1975 represented an incidence of approximately 25 per 100 000 hospital admissions (7 of these patients were previously described by Laurin and Kaude⁶ and 1 by Rizkallah et al⁷). There were 5 boys and 6 girls. The age at diagnosis ranged from 9 months to 17 years (mean, 7.5 years).

Clinical Data

The patients' symptoms and signs were nonspecific (Table 1). Abdominal pain was present in 10 (91%), fever in 9

(82%), and hepatomegaly in 8 (73%). The duration of the presenting symptom ranged from 1 to 90 days. Five patients presented with fever of unknown origin. The erythrocyte sedimentation rate was elevated (range, 32 to 122 mm/h; mean, 77 mm/h) in all 8 patients tested. Ten patients (91%) were anemic (hemoglobin level, 67 to 123 g/L; mean, 98 g/L) and 8 (73%) had leukocytosis (leukocyte count, 8.4 to 31.0 $\times 10^9$ /L; mean, 16.2 $\times 10^9$ /L). Alanine and aspartate aminotransferase levels were elevated in 3 patients (27%) (alanine aminotransferase levels, 112, 190, and 234 U/L; serum albumin level was low in 5 (45%) of 11 patients (27 to 33 g/L; mean, 30 g/L).

Five patients in our series had chronic granulomatous disease or leukemia that predisposed them to development of PLA. In two (patients 6 and 7), the underlying medical problems were unrelated to their liver abscess. Of the 11 patients, 4 had single and 7 had multiple abscess cavities. The abscesses were localized to the right lobe of the liver in 8 patients. *Staphylococcus aureus* was the organism most commonly isolated (Table 1). Anaerobes were cultured from the liver abscesses of 3 patients. One patient, with multiple small abscesses throughout the liver, had a positive cat-scratch skin test. His culture of liver tissue for bacterial and fungal agents was negative.

Diagnostic Findings

Ultrasonography, the most commonly employed imaging method, gave positive results in all eight patients studied. The lesions were hypoechoic in all but one patient, who had a mixed echo pattern. Usually the lesions were poorly delineated, although two patients (patients 4 and 10) had a rim of increased echogenicity around the abscess.

The technetium Tc 99m liver-spleen scan was positive in four patients, all with areas in the liver of reduced radio-

Table 1.—Clinical Data, Liver Abscess Culture, and Antibiotic Therapy in 11 Patients With Pyogenic Liver Abscess*

Patient/Age, y/Sex	Underlying Problems	Presenting Symptoms and Signs	Location and No. of Abscesses	Organisms	Antibiotics
1/2½/M	Chronic granulomatous disease	FUO, abdominal pain, hepatomegaly	R lobe, multiple	<i>Staphylococcus aureus</i> (liver)	Penicillin G potassium, gentamicin sulfate, methicillin sodium
2/14/F	None	FUO, abdominal pain, hepatomegaly	R lobe, multiple	<i>S aureus</i> (liver)	Methicillin, gentamicin
3/3/M	Chronic granulomatous disease	Fever, abdominal pain, hepatomegaly	R lobe, multiple	<i>S aureus</i> (liver)	Methicillin, metronidazole
4/13/M	Diabetes	R-sided chest pain, cough	R lobe, single	<i>Peptostreptococcus</i> (liver)	Penicillin
5/9½/F	Amebic liver abscess	Fever, vomiting, diarrhea, RUQ mass, hepatomegaly	R lobe, single	<i>Escherichia coli</i> (liver, peritoneal cavity)	Ampicillin, gentamicin, metronidazole
6/17/M	Sickle cell trait	Fever, abdominal pain	R lobe, single	<i>Peptostreptococcus</i> (liver)	Cefoxitin, penicillin
7/8/F	Recurrent UTI	FUO, abdominal pain, hepatomegaly	Both lobes, multiple	<i>Staphylococcus epidermidis</i> (liver)	Nafcillin sodium
8/2/F	None	Epigastric mass, abdominal distention	L lobe, single	<i>S aureus</i> (liver)	Nafcillin, cephalexin
9/3/M	Cat scratch disease	FUO, abdominal pain, hepatomegaly	Both lobes, multiple	None	Ampicillin, gentamicin, cefaclor
10/13/F	None	FUO, hepatomegaly, weight loss	R lobe, multiple	<i>S aureus</i> (liver)	Nafcillin
11/12/F	Perforated appendix, peritonitis	Fever, abdominal pain, vomiting	R lobe, multiple	<i>Bacteroides</i> , <i>Propionibacterium</i> (liver)	Penicillin, gentamicin

*FUO indicates fever of unknown origin; RUQ, right upper quadrant; and UTI, urinary tract infection.

activity. The gallium 67 scan performed in two children was normal. More recently, computed tomography (CT) of the liver was done in five children; the findings were abnormal in all cases, showing areas of reduced density within the liver. The CT scan provided the best definition of all three imaging modalities used. The diagnosis was confirmed by exploratory laparotomy and percutaneous aspiration of purulent material in six and five patients, respectively.

Treatment

In most patients, treatment consisted of the combination of a drainage procedure and appropriate broad-spectrum antibiotic therapy (Table 1). All patients were treated for 4 to 8 weeks with different combinations of parenteral and oral antibiotics. Six children (patients 1, 2, 5, and 7 through 9) had open drainage of their liver abscesses during laparotomy. The 1 patient (No. 5) with both PLA and amebic abscess was the only patient (1 of 11) who did not survive. Since 1980, four patients (Nos. 4, 6, 10, and 11) underwent successful percutaneous abscess drainage; fluoroscopic guidance was used for two of these patients. One (patient 3) did not require a drainage procedure. Recently, ultra-

sonography and CT scans have been the preferred methods of localization before the drainage procedure. The catheters were left in place for 2 to 3 weeks, until purulent material ceased to drain and the abscess cavity significantly decreased in size (Figure). Percutaneous drainage was effective in the four patients in whom it was attempted, and they all survived.

Previously Described Patients

During the same period of our experience, 98 children with PLA were described in the pediatric literature,⁸⁻⁴⁷ as catalogued by the National Library of Medicine. Together with our 11 patients, 67% were boys and 33% girls. Fifty-five percent of the 109 children were more than 5 years of age. Leukemia and chronic granulomatous disease were the most common predisposing conditions. The lesions were equally divided between single and multiple liver abscesses; they were localized to the right lobe of the liver in 73% of the patients. *Staphylococcus aureus* was the most commonly isolated organism. Enteric gram-negative bacteria accounted for 26 (31%) of 82 isolates, while anaerobes were recovered in 15% of the pa-

Upper-abdominal computed tomographic scans in patient 11 after contrast enhancement. Top, Two low-density oval lesions in the right lobe of the liver (black arrows). Bottom, Scan of the same patient after placement of percutaneous drainage catheter (open arrow).

tients. Excluding a large autopsy study of neonates,² infant and child mortality was 15%.

Diagnostic imaging techniques included radioisotope scanning, ultrasonography, CT scans, and angiography (Table 2). Overall, they were all sensitive investigations, especially the angiography, but it was done in only 9 of the 109 patients. The CT scans failed to identify the lesion in only 1 patient with multiple microabscesses. Neither ultrasonography nor radioisotope scanning proved to be as sensitive as CT scans, giving false-negative results in 12 (21%) of 58 and 8 (19%) of 43 patients, respectively. For the radioisotopic scans, gallium 67 failed to yield a diagnosis in 5 (38%) of 13 patients, and the technetium Tc 99m scan was falsely negative in 4 (9%) of 45. The diagnosis of liver abscess was confirmed by laparotomy in 56% of patients, by percutaneous aspiration in 24%, and at autopsy in 20%.

Laparotomy with open drainage was the procedure most commonly performed (Table 3). It was done in 46 patients, with a mortality of 11%. Percutaneous drainage of the liver abscess was accomplished in 11 patients, all of whom survived. In one patient, the percutaneous procedure was unsuccessful, necessitating open drainage to evacuate the abscess adequately.⁴⁵ Failure to drain the purulent material was accompanied by a high mortality: 20 (47%) of 43 patients died. In 17 of 20 patients who died without a drainage procedure, the diag-

nosis was made at autopsy. The majority of the 23 survivors in this latter group had multiple microabscesses that were treated with antimicrobial agents.

COMMENT

Review of our experience from 1975 to 1986 and a literature survey since 1977 revealed 109 well-documented cases of PLA in patients less than 18 years of age, compared with 61 children described between 1935 and 1977.³ This higher incidence of PLA in children during the past decade compares more closely with rates noted for adults with this disease.^{4,5} For adults and children, the incidence may be due, in part, to the improved imaging techniques available to diagnose PLA in some patients in whom it was previously unrecognized. Another reason may be the improved survival of patients with chronic granulomatous disease and leukemia who are at risk for developing liver abscesses. The prolonged lifespan of patients with primary and secondary immune defects could also account for older children with PLA since 1977. Approximately 50% of the 109 patients were more than 6 years of age, in contrast to reports before 1977, in which 66% of the patients were less than 5 years old.^{1,3}

In the last decade, newer imaging techniques have made for earlier diagnosis of PLA in children, who usually have a nonspecific clinical presentation. Angiography, an invasive procedure that may yield nonspecific findings, is almost never necessary to diagnose PLA in children. The CT scans of the liver provided the best sensitivity and specificity of all imaging techniques for our patients and those described in recent studies. Detailed images can be obtained due to its high resolution.⁴⁶ Ultrasonography and radioisotope scans are, overall, not as sensitive. However, among our 11 patients, the liver ultrasound scan was positive in all 8 patients studied.

Once a cystic mass is identified in the liver, diagnostic considerations other than pyogenic abscess include congenital cyst, arteriovenous malformation, hepatic tumor with central necrosis or hemorrhage, and amebic abscess. This last diagnosis is the most important differential diagnostic consideration. In many parts of the world, amebic abscess is a far more frequent diagnosis than

PLA. In addition to ethnicity, patients with amebic abscess are more likely to have abdominal pain and a history of diarrhea, but the signs and symptoms often mimic those of PLA. Abdominal CT scan is the best method of detecting amebic liver abscess and its extrahepatic abnormalities, such as pleural effusion and amebic colonic involvement. Most importantly, the presence of an elevated amebic antibody titer in the setting of a hepatic abscess is diagnostic of amebic abscess.

In the appropriate clinical setting, the diagnosis of PLA must be confirmed by aspiration of purulent material from the suspected abscess cavity. A percutaneous aspiration with ultrasound or CT guidance can be accomplished if the size and location of the abscess make it feasible.⁴⁶ Since 75% of the abscesses are located in the right lobe of the liver, a percutaneous aspiration can be considered in the majority of children.

The choice of antibiotics is determined by the results of the culture and corresponding sensitivity studies. *Staphylococcus aureus* remains the single most common cause of PLA. Enteric gram-negative organisms taken as a group are as frequent as *S aureus*. Anaerobes, identified in 27% of children in our small series and 15% of the 109 patients, are a third major group of pathogens. For children, this is in contrast to the rare report before 1977 of hepatic abscess due to anaerobic bacteria—probably a direct result of improved diagnostic culture techniques since that time.^{4,5} Although pleomorphic gram-negative bacilli were not cultured from any tissue of our patients, one child (patient 9) had a positive cat-scratch test after a well-documented scratch by an animal before the development of acute disease. Liver abscesses complicating cat-scratch disease should be considered even in the absence of abnormal results of liver function tests.⁷

Furthermore, if the abscess is located in the right lobe of the liver and has a well-defined cavity, drainage by percutaneous catheter should be attempted.⁵⁰ Adult patients with PLA have been successfully treated by repeated needle aspiration.⁵¹ The first continuous closed drainage in a patient with PLA was performed many years later.⁵² Recently, adults and children were treated by percutaneous drainage or aspiration of the

Total	25/109*	23

*Insufficient information on 9 of 109.

abscess cavity^{30,53}; in one study, the procedure was effective in 58 patients and the mortality was 1.5%.³⁰ While pediatric experience is limited, the recent adult literature suggests that percutaneous drainage should be the initial therapy for patients with PLA.^{54,55} However, despite a well-documented record of efficacy, reasons for the limited use of closed drainage procedures in adults are unclear. This may, in part, be related to the role of percutaneous drainage in patients with multiple large PLAs, in whom the mortality from PLA is at least doubled.⁵⁶ Specific disadvantages include complications and failure of the procedure due to technical problems and occasionally a prolonged hospital admission when compared with medical or surgical treatment alone.^{54,57}

In summary, PLA should be suspected in any child with unexplained, persistent fever; abdominal pain; and hepatomegaly. If a cystic cavity is found within the liver parenchyma by ultrasonography or CT scan, aspiration of the lesion should be considered to confirm the diagnosis. In the majority of patients it is usually feasible to attempt percutaneous drainage initially, except in those patients with multiple microabscesses or left-lobe abscesses. The more recent improved outcome for children with PLA may be secondary to earlier diagnosis with prompt drainage of the abscess and precise antibiotic therapy. Careful attention should always be given to the isolation of anaerobic organisms from the cystic cavity of the liver. Amebic liver abscess is another important diagnosis to exclude with hemagglutination/complement fixation tests. A skin test with cat-scratch antigen is also necessary, especially for those children with multiple microabscesses.

(metaproterenol sulfate)

Bronchodilator

Tablets 10 and 20 mg	Inhalation Aerosol 10 mL	Syrup 10 mg/5 mL	Inhalation Solution 5%	Inhalation Solution Unit-dose Vials 0.4% and 0.6%
----------------------------	--------------------------------	---------------------	------------------------------	--

Brief Summary of Prescribing Information

CONTRAINDICATIONS Use in patients with cardiac arrhythmias associated with tachycardia is contraindicated.

Although rare, immediate hypersensitivity reactions can occur. Therefore, Alupent® (metaproterenol sulfate USP) is contraindicated in patients with a history of hypersensitivity to any of its components.

WARNINGS Excessive use of adrenergic aerosols is potentially dangerous. Fatalities have been reported following excessive use of Alupent® (metoprolol sulfate USP) as with other sympathomimetic inhalation preparations, and the exact cause is unknown. Cardiac arrest was noted in several cases.

Alupent, like other beta adrenergic agonists, can produce a significant cardiovascular effect in some patients, as measured by pulse rate, blood pressure, symptoms, and/or ECG changes. As with other beta adrenergic aerosols, Alupent can produce paradoxical bronchospasm (which can be life threatening). If it occurs, the preparation should be discontinued immediately and alternative therapy instituted.

Alupent® (metaproterenol sulfate USP) should not be used more often than prescribed. Patients should be advised to contact their physician in the event that they do not respond to their usual dose of a sympathomimetic amine aerosol.

PRECAUTIONS General: Extreme care must be exercised with respect to the administration of additional sympathomimetic agents.

Since metaproterenol is a sympathomimetic amine, it should be used with caution in patients with cardiovascular disorders, including ischemic heart disease, hypertension or cardiac arrhythmias, in patients with hyperthyroidism or diabetes mellitus, and in patients who are unusually responsive to sympathomimetic amines or who have convulsive disorders. Significant changes in systolic and diastolic blood pressure could be expected to occur in some patients after use of any beta adrenergic bronchodilator.

Information for Patients: Extreme care must be exercised with respect to the administration of additional sympathomimetic agents. A sufficient interval of time should elapse prior to administration of another sympathomimetic agent.

Drug Interactions: Other beta adrenergic aerosol bronchodilators should not be used concomitantly with Alupent because they may have additive effects. Beta adrenergic agonists should be administered with caution to patients being treated with monoamine oxidase inhibitors or tricyclic antidepressants, since the action of beta adrenergic agonists on the vascular system may be potentiated.

Carcinogenesis/Mutagenesis/Impairment of Fertility: In an 18-month study in mice, Allupent produced an increase in benign ovarian tumors in females at doses corresponding to 320 and 640 times the maximum recommended dose (based on a 50 kg individual). In a two-year study in rats, a non-significant incidence of benign leiomyomata of the mesovarium was noted at 640 times the maximum recommended dose. The relevance of these findings to man is not known. Mutagenic studies with Allupent have not been conducted. Reproduction studies in rats revealed no evidence of impaired fertility.

Pregnancy *Teratogenic Effects: Pregnancy Category C:* Alupent® (metaproterenol sulfate USP) has been shown to be teratogenic and embryotoxic in rabbits when given orally in doses 620 times the human inhalation dose and 62 times the human oral dose. There are no adequate and well-controlled studies in pregnant women. Alupent should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Oral reproduction studies in mice, rats and rabbits showed no teratogenic or embryocidal effects at 50 mg/kg, corresponding to 310 times the human inhalation dose and 31 times the human oral dose. Teratogenic effects in the rabbit included skeletal abnormalities and hydrocephalus with bone separation on

Nursing Mothers: It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Alupent* (metaproterenol sulfate USP) is administered to a nursing woman.

Pediatric Use Consult package insert for age limit

ADVERSE REACTIONS Adverse reactions are similar to those noted with other sympathomimetic agents. Adverse reactions such as tachycardia, hypertension, palpitations, nervousness, tremor, nausea and vomiting have been reported.

The most frequent adverse reaction to Alupent® (metaproterenol sulfate USP) administered by metered-dose inhaler among 251 patients in 90-day controlled clinical trials was nervousness. This was reported in 6.8% of patients. Less frequent adverse experiences, occurring in 1-4% of patients were headache, dizziness, palpitations, gastrointestinal distress, tremor, throat irritation, nausea, vomiting, cough and asthma exacerbation. Tachycardia occurred in less than 1% of patients.

HOW SUPPLIED *Inhalation Aerosol:* Each Alupent® Inhalation Aerosol contains 150 mg of metaproterenol sulfate as a micronized powder in inert propellants. Each metered dose delivers through the mouthpiece 0.65 mg. metaproterenol sulfate (each mL contains 15 mg). Alupent Inhalation Aerosol with Mouthpiece (NDC 0597-0070-17), net contents 14g (10mL), equipped with blue protective cap. Alupent Inhalation Aerosol Refill (NDC 0597-0070-18), net contents 14g (10 mL).

Store between 59°F (15°C) and 77°F (25°C). Avoid excessive humidity.

Inhalation Solution: Alupent Inhalation Solution is supplied as a 5% solution in bottles of 10 mL or 30 mL with accompanying calibrated dropper. Store below 77°F (25°C). Protect from light. Do not use the solution if it is brown or has a precipitate.

Alupent Inhalation Solution Unit-dose Vial is supplied as a 0.4% or 0.6% clear colorless or nearly colorless solution containing 2.5 mL, with 25 vials per box. Store below 77°F (25°C). Protect from light. Do not use the solution if it is brown or has a precipitate.

Syrup: Alupent is available as a cherry-flavored syrup, 10 mg per teaspoonful (5 mL), in 16 fl. oz. bottles. Store below 86°F (30°C). Protect from light.

Tablets: Alupent is supplied in two dosage strengths as scored, round white tablets in bottles of 100. Tablets of 10 mg coded B1/74. Tablets of 20 mg coded B1/72.

Storage for bottles: Store below 86°F (30°C). Protect from light

Storage for blister samples: Store below 77°F (25°C). Protect from light.

Fetal Surgery in the 1990s

Mark I. Evans, MD; Arie Drugan, MD; Frank A. Manning, MD; Michael R. Harrison, MD

In the recent past, the first opportunity to visualize fetal structure and function occurred at birth. Two major contributions in the 1960s inaugurated the era of the *fetus* as a patient: (1) Prenatal diagnosis became possible using amniocentesis as a technique to evaluate fetal health by cytogenetic¹ and biochemical^{2,3} analysis. (2) Prenatal treatment became possible using fetal transfusion to control rhesus factor erythroblastosis fetalis.⁴ Intrauterine exchange transfusions through an open abdomen and uterine incision were attempted and abandoned due to unacceptably high maternal morbidity associated with "open" procedures.⁵ The development of less invasive techniques for percutaneous placement of catheters or needles for intraperitoneal transfusion permitted in utero exchange transfusion.⁶

In the 1970s, the introduction of fetal ultrasonography allowed for accurate visualization of the structure and function of the fetus.⁷ As skill and technology advanced, the list of fetal anomalies able to be diagnosed by ultrasonography expanded.⁸ Maternal serum α -fetoprotein screening⁹ has increased the ability to detect some anomalies that might not otherwise have been detected. The combination of ultrasonography with maternal serum α -fetoprotein

screening⁹ allows for prenatal diagnosis of anomalies of the fetal neural tube, abdominal wall, urinary system, or the lymphatic system (ie, cystic hygroma). After the diagnosis of a fetal anomaly prior to 24 weeks' gestation, parents have a choice between termination of pregnancy or preparing for the birth of an "affected child." It is our belief that parents should be told of the option of abortion; no matter how serious the anomaly, the option must always be presented to the parents when legally permissible. If the pregnancy is continued, knowledge of the defect has potential psychological advantages for the parents and definite logistic advantages for the pediatric staff who will care for the infant after birth.

In a very limited number of circumstances, there may be another option, ie, treatment before birth. Both surgical and medical approaches have been attempted. We will review the status of surgical interventions. Other reviewers have dealt with the cardiac¹⁰ and biochemical¹¹ aspects of medical fetal therapy and the potential for gene therapy.¹²

When a potentially correctable fetal anomaly is diagnosed, the following factors must be considered:

1. What is the natural outcome of this anomaly? Will additional or irreversible damage be caused to the fetus if repair procedures are delayed until after birth?

2. Is it possible to correct the anomaly or its consequences in utero? Will the procedure change the natural outcome?

3. What is the risk to the mother and the fetus?

Surgical intervention in utero should be considered only if the natural history of the anomaly is associated frequently with neonatal severe handicap or early death, if there is evidence (from animal

models) that the natural history of the anomaly can be altered by the surgical procedure, and if the risk to the mother is relatively small as proved in a rigorous animal model (eg, the nonhuman primate).

In the early 1980s, investigators identified several fetal diseases in which a simple anatomic defect interferes with organ development and might be amenable to correction: hydronephrosis, hydrocephalus, and diaphragmatic hernia.^{13,14} The International Fetal Medicine and Surgery Society began meeting in 1982 and formulated guidelines for fetal intervention.¹⁵ They also established a registry to record all cases of obstructive uropathy and obstructive ventriculomegaly in which in utero operative procedures were undertaken. Registries for fetal medical treatment, cardiac arrhythmias, chylothorax, etc, have since been established, and reports are published periodically.¹⁶

FETAL VENTRICULOMEGALY

In the early 1980s, much of the focus of the potential for fetal therapy centered on obstructive ventriculomegaly. Interest in this disorder emerged from the relative ease to diagnose such anomalies by then-available ultrasound technology and was amplified by the success rates of shunting procedures performed in the neonate.¹⁷ The concept, as developed in animal models, was that early shunting of ventriculomegaly in utero might prevent the irreversible damage caused by prolonged increased intracranial pressure.¹⁸⁻²⁰ In humans, however, the results of ventriculoamniotic shunts were very disappointing. As of July 1, 1989, 45 cases of fetal ventriculomegaly treated in utero by long-term ventriculoamniotic shunts were reported to the International Fetal Registry (Table 1).¹⁶

Accepted for publication June 13, 1989.

From the Division of Reproductive Genetics, Departments of Obstetrics/Gynecology and Molecular Biology and Genetics, Hutzel Hospital, Wayne State University, Detroit, Mich (Dr Evans); the Department of Obstetrics and Gynecology, Ram Bam Medical Center, Haifa, Israel (Dr Drugan); the Department of Obstetrics and Gynecology, University of Manitoba, Winnipeg, Canada (Dr Manning); and the Fetal Treatment Program and Division of Pediatric Surgery, University of California, San Francisco (Dr Harrison).

Reprint requests to Division of Reproductive Genetics, Hutzel Hospital, 4707 St Antoine Blvd, Detroit, MI 48201 (Dr Evans).

In the majority of instances, the shunting was performed for a fetus presumed to have ventriculomegaly-hydrocephalus secondary to aqueductal stenosis. The mean (\pm SD) gestational age at diagnosis was 25 ± 2.73 weeks (range, 18 to 31 weeks), and the mean age at treatment was 27 ± 2.6 weeks (range, 23 to 33 weeks). The duration of effective therapy cannot be determined from Registry data since objective means of assessment of shunt function are not available. Thirty-four (83%) of 41 fetuses with hydrocephalus treated by ventricular amniotic shunting have survived. Of the 7 deaths that occurred, 4 could be directly attributed to trauma at the time of placement of the shunt or to premature labor occurring within 48 hours of shunt placement. The crude mortality rate for the procedure is, therefore, 9%. The 38 surviving infants have been followed up on average for 12.2 ± 5.8 months (range, 6 to 36 months). Fourteen (35.3%) of the 34 surviving fetuses, all with aqueductal stenosis, are reported as "normal" at follow-up (Table 2). The remaining 24 survivors have all exhibited varying degrees of neurological handicap, the majority of whom (18 [53%] of 34 survivors) are classified as having severe handicaps. These infants all exhibited gross delay in reaching developmental milestones, and the tested developmental quotient was always less than 60. Five of these infants have had cortical blindness, 3 have had seizure disorders, and 2 have spastic diplegia. Outcome among survivors was principally related to the primary cause of obstructive hydrocephalus. Aqueductal stenosis of uncertain origin was the most common causative factor for obstructive hydrocephalus (28 [68%] of 41 cases), and the only intact survivors were found in this group.

The results of ventriculoamniotic shunting for fetal ventriculomegaly, therefore, have been quite disappointing, and there are no one-way valve shunt devices available even if one wanted to treat a patient; thus, there is a "de facto" moratorium in place.^{21,22} The hope, which was to take fetuses that would otherwise be severely impaired by ventriculomegaly and to avoid irreversible damage by intrauterine treatment, was substituted in a few unfortunate instances, with survival of se-

Primary Diagnosis (Postnatal)	No. of (% of Total) Cases	No. of Deaths	Mortality by Diagnosis, %	No. of Survivors	Survival by Diagnosis, %
Aqueductal stenosis	32 (76.9)	4	13.3	28	87.5
Associated anomalies	5 (12.7)	2	40	3	60

Total	34	12 (35.3)	4 (11.8)	18 (52.9)

verely affected infants who would have otherwise mercifully died.

Despite the seemingly poor outcomes in treated fetuses, abandonment of the concept of shunting for ventriculomegaly must be reconsidered for several reasons. Analysis of the cases of ventriculoamniotic shunt placement performed in the 1980s reported in the Registry shows that selection criteria were not always employed appropriately, and fetuses with ventriculomegaly associated with other severe anomalies (ie, holoprosencephaly or autosomal trisomies) were also, in many instances, given the "benefit" of intrauterine treatment.

Current reports have also demonstrated that the natural history of fetal ventriculomegaly is also quite dismal.^{23,24} The major determinant of prognosis was the association with other intracranial or extracranial malformations. Additional malformations affect

70% to 85% of fetuses with ventriculomegaly, and all such cases end in perinatal mortality or severe morbidity. Moreover, even if a diligent search for additional malformations is performed, combining a detailed ultrasound study of the fetus with amniocentesis for karyotype and amniotic fluid α -fetoprotein and acetylcholinesterase, 20% to 40% of abnormalities will not be detected even by experienced personnel.^{23,24} The obvious candidates for in utero ventricular shunt—the fetuses with isolated progressive ventriculomegaly—are limited in number by a high rate of associated anomalies and by the relative failure to exclude additional malformations prenatally. Moreover, the severity of ventriculomegaly is not always predictive of outcome or even of the need for postnatal shunt, as ventriculomegaly may not be associated with elevated intracranial pressure.

Considering the uncertainties of benefit and risk and the difficulties of accurate prenatal diagnosis, intrauterine treatment of fetal ventriculomegaly remains a controversial and highly experimental procedure. However, when the option in midtrimester is between termination of pregnancy or inactive observation of progressive dilatation of the ventricles, placement of a ventriculoamniotic shunt should present a third option to be considered in very selected cases.²² Given the small numbers of "good" candidates and the need to develop a new catheter (as none is currently available), a new study would be best performed in only one or two centers in North America experienced in the technical aspects of ventriculoamniotic shunt placement. Obviously, this experience is now lacking when there exists a de facto moratorium on intrauterine treatment of ventriculomegaly. It is hoped that there can now be a reconsideration and study of ventriculomegaly shunting that may answer the question of its usefulness for the limited number of appropriate patients.²⁴

OBSTRUCTIVE UROPATHY IN THE FETUS

The widespread use of obstetric ultrasonography and the increase in resolution and technical expertise allow the recognition of obstructive uropathy more frequently and earlier in pregnancy.^{24,25} Retrograde pressure forms behind the obstruction and causes increasing dilatation of the urinary system. As documented in animal studies, hydronephrotic and, perhaps, dysplastic changes occur in the renal parenchyma.²⁶⁻²⁹ The severe oligohydramnios associated with bilateral urinary tract obstruction results in pressure deformities of the face and limbs and pulmonary hypoplasia; neonatal death is caused by respiratory insufficiency. The timing and the degree of obstruction are crucial determinants in the development of irreversible renal and pulmonary damage.^{30,31}

Intrauterine treatment should be reserved for patients with bilateral urinary tract obstruction, maintained renal function, decreased amniotic fluid volume, and no other life-threatening anomalies. Cytogenetic anomalies and congenital malformations of other systems are diagnosed in 15% to 40% of

cases of fetal obstructive uropathy.^{32,33} The evaluation should include the karyotype (by amniocentesis, transabdominal chorionic villus sampling, or cordocentesis), echocardiography, and a detailed ultrasound examination to assess renal size or dysplastic changes, to evaluate fetal bladder filling, and to exclude additional malformations. If fetal visualization is hampered by severe oligohydramnios, artificial instillation of fluid will improve sonographic visibility and the observation of fetal behavior (drinking, filling of stomach and bladder), allowing more accurate study of the fetal anatomy.³⁴

The evaluation of fetal renal function is based on ultrasonographic observation of bladder filling (after urine aspiration), absence of renal cortical cysts, and analysis of urine osmolality and electrolytes.³⁵ None of these tests are, however, infallible. The bladder may fill from secretion by bladder mucosa. The ultrasonic demonstration of renal cortical cysts has a specificity of 100% and a sensitivity of 44% in identifying renal dysplasia with irreversible damage.³⁶ Hypotonic fetal urine (sodium, <100 mmol/mL; chlorine, 90 mmol/mL; osmolality, <210 mmol/L) suggests maintained glomerular and tubular function. However, while abnormal electrolyte levels and osmolality in fetal urine are associated with poor prognosis in the vast majority of cases, hypotonic urine does not reliably exclude the finding of dysplasia or neonatal evidence of severe renal dysfunction.^{31,37} Urinary electrolytes normally drop with gestational age (C. Rodeck, MD, oral communication, July 8, 1989).

Dumez et al³⁸ have evaluated multiple urinary variables and found β_2 -microglobulin, ammonia, and creatinine, to be good predictors of renal function and long-term outcome. Overall, the best ultrasonic indicator of the severity of the disease appears to be the decrease in amniotic fluid volume. When the fetus develops severe oligohydramnios before the 20th week of gestation, the prognosis is most commonly dismal.³⁵

Most procedures of vesicoamniotic shunt placement have been performed percutaneously under ultrasonographic guidance. A double-coiled nylon catheter was used in most cases with good results. Unlike brain shunts, one-way

valve catheters are not necessary since the pressure in the obstructed bladder almost always exceeds that in the amniotic fluid.

The function of these shunts may, however, be impaired by occlusion or displacement, necessitating close observation and replacement of the non-functioning shunt. When weeks to months of continuous drainage are required, some favor open surgical decompression by bladder marsupialization or bilateral ureterostomies.^{35,39-41} This would involve, however, an increased risk for both mother and fetus. Of the 87 cases of fetal obstructive uropathy reported to the Registry as of July 1, 1989, there have been 35 survivors (40.2%) (Table 3). The oldest survivor is now 7 years of age and appears to be developing normally. The mean (\pm SD) gestational age at initial referral has been 23 ± 4.6 weeks (range, 14 to 34 weeks). The mean age at in utero therapy has been 24.2 ± 5 weeks (range, 14 to 36 weeks). No uniformity in shunt design, construction material, or method of shunt placement is recorded. Of the 87 cases, 13 (14.9%) were electively terminated after shunt placement. In 7 of these instances, termination was elected because of abnormal karyotype, and in 6 instances because of a suspected or proved major renal dysfunction. Of the remaining 74 ongoing pregnancies, there have been 35 fetal survivors (47.3%). Perinatal survival is strongly related to the primary cause of obstructive uropathy, and the criteria for diagnosing the cause of the disease have continued to improve. The best survival is reported among fetuses with proved posterior urethral valve syndrome (68%).

The long-term follow-up data of these children are now becoming available. To date, chronic morbidity is being reported in only 3 (8.6%) of 35 survivors. One of these children with post-urethral valve syndrome has developed chronic renal failure requiring hemodialysis. One survivor has borderline renal function and chronic pulmonary insufficiency that is progressed at 2 years of age. A third female child has required extensive and ongoing corrective surgery for a persistent cloacal syndrome. The operative mortality rate remains relatively constant. The death rate directly at-

Table 3.—Fetal Obstructive Uropathy: Primary Diagnosis and Outcome in 87 Treated Cases*

Primary Diagnosis	No. of (% of Total) Cases	No. of Survivors	Survival by Diagnosis, %
Posterior urethral valve syndrome	25 (28.7)	17	68
Karyotype abnormality†	7 (8)	0	0
Renal dysplasia noted by ultrasound†	6 (6.9)	0	0
Urethral atresia	6 (6.9)	1	20
Prune-belly syndrome	5 (5.7)	4	16.7
Unknown	1 (1.1)	1	100
Ureteropelvic obstruction	2 (2.3)	2	100
Unknown origin	35 (40.2)	10	28.6
Total	87 (100)	35	40.2

*Primary diagnosis was confirmed by antenatal or neonatal assessment or by autopsy.

†In these cases, pregnancy was electively terminated.

tributable to vesicoamniotic shunting has been 4.7% (4/85 cases).

These data may be interpreted to suggest that there is a defined role for chronic vesicoamniotic shunting in fetuses with bilateral hydronephrosis secondary to urethral obstruction (usually male patients with posterior urethral valves). To be appropriate candidates, fetuses must (1) have normal karyotypes and have progressive and persistent disease, (2) have time to develop pulmonary tissue, (3) have good prognostic criteria (good fetal urine electrolytes and osmolality), and (4) have normal renal parenchymal echogenicity without cysts at the time of preoperative assessment.

It is apparent in reviewing the recent data referred to the Registry¹⁶ that much more selective criteria are being used now before a patient is considered a candidate for fetal surgery. Most notably, use of fetal urinary electrolyte levels and osmolality have had a major discriminating effect. As a result, survival in treated fetuses is continuing to improve, whereas the proportion of evaluated fetuses being treated continues to fall.

OPEN FETAL SURGERY

While the percutaneous approach under ultrasonographic guidance seems to be the preferred method for placing a shunt in a hollow enlarged viscus, the correction of more extensive fetal anomalies will require more extensive and more invasive surgery on both

mother and fetus. The feasibility of open fetal surgery was anecdotally demonstrated in the 1960s when an open technique was used for intrauterine exchange transfusions in erythroblastosis fetalis.⁴² However, preterm labor and abortion made this initial experience so discouraging that direct exposure of the fetus was abandoned for over a decade. In the late 1970s and early 1980s, interest in open fetal surgery was revived by two factors. Prenatal diagnosis of some simple anatomic defects with disastrous consequences for the developing fetus (eg, fatal pulmonary hypoplasia secondary to urinary tract obstruction or diaphragmatic hernia) was being recognized. At the same time, neonatologists and pediatric surgeons were coming to grips with the futility of attempting to salvage these infants after birth. It is most important to note that the outcome of some prenatally detected conditions such as diaphragmatic hernia is markedly different from that of the "same" postnatally detected lesion. While the survival of postnatally detected diaphragmatic hernia is high, the prenatally detected condition is worse and has at best a 20% survival.⁴³⁻⁴⁵

It became apparent that the only way to salvage fetuses with these lesions was open surgery. However, the open approach could be justified only if the following criteria were met:

1. The natural history of the human fetal disorder is defined and selection of only those fetuses with the disorder who are likely to benefit from intervention is possible.

2. The pathophysiologic structure of the disorder and the efficacy of in utero correction were established in animal models.

3. The proposed procedure was proved feasible and safe for both fetus and mother in a rigorous, nonhuman primate model. Extensive experience with fetal surgery in sheep and phylogenetically lower animals could not be used to evaluate the feasibility and safety of fetal intervention in humans because the biological gestation is dissimilar and hysterotomy seldom induces preterm labor and abortion. The primate uterus, on the other hand, is exquisitely sensitive to surgical manipulation, making success in this model a rigorous criteria for human application.

In the early 1980s, a group in San Francisco, Calif, satisfied these criteria by studying the pathophysiologic structure of diaphragmatic hernia⁴⁶⁻⁴⁸ and hydronephrosis²⁶⁻³⁰ in animals, by defining the natural history and outcome of diaphragmatic hernia⁴³⁻⁴⁵ and obstructive uropathy^{35,39-41} in human fetuses, and by developing the anesthetic, pharmacologic, and surgical techniques in the nonhuman primate necessary to make open fetal surgery safe for both mother and fetus.⁴⁹⁻⁵¹ The techniques developed in the laboratory have been applied to 12 highly selected human cases (5 uropathies,⁵² 6 diaphragmatic hernias,⁵³ 1 sacrococcygeal teratoma⁵⁴) by Harrison et al since 1982. Four procedures were technically unsuccessful and a fetectomy was performed; in the other 6, the fetus survived and was eventually delivered by a second cesarean section. The details of these initial cases have been reported.⁵²⁻⁵⁴ The most important aspect in this initial phase 1 trial of open fetal surgery was maternal safety. There were no significant intraoperative complications. Operative blood loss ranged from 200 to 1000 mL, but none of the patients required transfusion. There were no wound infections or complications, and hospital stay following fetal surgery varied from 5 to 13 days (mean, 7.7 days). Two patients developed amniotic fluid leaks postoperatively that were due to the technique of uterine closure, which has since been corrected. The most common postoperative problem was uterine irritability, and all patients required tocolytic therapy. Pre-

mature labor remains a constant threat and is the major morbidity associated with fetal surgery. Four of these patients have had subsequent normal pregnancies, suggesting that fetal surgery does not interfere with reproductive capacity. Of these initial cases, all of the patients with uropathy have survived with variable renal function. Of the initial patients with diaphragmatic hernias, the first three were technically unsatisfactory. The last was delivered at 31 weeks, and the infant did well for several weeks. At 5 weeks post partum, a second operation was performed to remove the abdominal patch. Unfortunately, 2 days later, following an intubation accident, the infant died. Three of these patients have had subsequent normal pregnancies, suggesting that fetal surgery does not interfere with reproductive capacity.

These first cases of open fetal surgery represent a steep learning curve, but the overall experience argues for continued cautious application of these surgical procedures. Open fetal surgery is technically difficult but feasible, and thus far it has proved safe for mother and her reproductive potential. The efficacy of these procedures in reversing potentially fatal fetal maldevelopment remains to be proved.

FETAL SURGERY: AN OVERVIEW

Improvement in ultrasound technology and increased use of maternal serum α -fetoprotein screening in the last decade have resulted in the prenatal diagnosis of many disorders for which prenatal treatment could improve outcome. The experience with ultrasound-guided, percutaneous procedures developed for the treatment of erythroblastosis fetalis has proved this method to be safe for both fetus and mother. The success of the less-invasive shunt techniques has contributed to the shift of

interest away from more-invasive open fetal surgery.⁵⁵ It is clear, however, that the correction in utero of lesions that are more complex in nature, such as congenital heart lesions, diaphragmatic hernia, or meningomyelocele, will necessitate open forms of surgery.^{55,56} Although open fetal surgery appears to be relatively safe in terms of pregnancy loss or uterine rupture in pregnancy, it still involves the mother in two major surgical procedures within a relatively short period—one for fetal treatment and the other for cesarean delivery. The morbidity and mortality associated with major surgery during pregnancy are considerable.⁵⁷ Presently, state-of-the-art open fetal surgery is still a highly experimental procedure. Fetal surgery represents a formidable undertaking whose short- and long-term risks and benefits need to be documented and studied. Studies should continue on animal models aiming to improve the technical aspects and increase fetal and maternal safety of open fetal surgery; demonstrated success in the nonhuman primate model should be a requisite for any center to attempt open fetal surgery in humans. The initial cautious attempts to correct a few carefully selected lesions (diaphragmatic hernia, sacrococcygeal teratoma, severe uropathy) should continue only in those few centers dedicated to developing this experimental technique. As with other procedures of highly experimental nature, the need for institutional review board review, a detailed informed consent, honest and pragmatic parental counseling, and meticulous documentation and follow-up of every case cannot be overemphasized.

Percutaneous placement of amniotic shunts seems to be relatively safe, thereby shifting the risk ratio in favor of these procedures. Problems of accurate diagnosis and patient selection do, however, affect the success rate and ulti-

mate outcome. Fetuses affected by posterior urethral valves and isolated ventriculomegaly have the best chances of intact survival. Although excluding all associated anomalies is difficult and sometimes impossible, the minimal requirements before counseling intrauterine fetal therapy should include a satisfactory level III ultrasound, echocardiography, and fetal karyotype. A functional evaluation of the organ involved is also important. While urinalysis, rate of bladder filling, and ultrasonographic appearance of the kidneys may give an indication of whether fetal renal function is already irreversibly damaged, more subtle tests are needed to prove that fetal renal function is maintained. Likewise, the degree of ventricular dilatation, the cerebral mantle width, or even the progression of the process do not seem to correlate well with the need for shunt placement after birth or with subsequent intelligence.²³ Functional assessment of in utero intracranial disease may be possible; visual evoked potential in the fetal lamb appear to correlate with hypoxia, intracranial pressure, and hydrocephaly.⁵⁸

The problems of patient selection and diagnostic accuracy need to be solved during the coming years. While the answer to the "on whom to operate" question seems clear, an educated decision on which fetus to operate (and, more importantly, on which fetus *not* to operate) in utero is expected to result from the cumulative experience with fetal surgery during the next years. During this formative period for fetal surgery, it is vitally important that every case of fetal surgery is reported in detail to the Registry. Intrauterine fetal surgery is here to stay. Its future depends on cooperation and team approach. If properly applied, fetal surgery could improve the length and quality of life of some fetuses that otherwise would have lost the race even before reaching the starting line.

Clinical Predictors of *Chlamydia trachomatis* Endocervicitis in Adolescent Women

Looking for the Right Combination

Gary Remafedi, MD, MPH, Sue Ellen Abdalian, MD

• Chlamydial disease in adolescent women is a serious public health problem, but secondary preventive efforts through early detection and treatment are encumbered by the cost and complexity of mass screening. This study was undertaken to identify clinical predictors of infection that might narrow the scope of screening adolescent populations. Demographic/clinical data and endocervical smears for the direct-specimen fluorescein-conjugated monoclonal antibody test for *Chlamydia trachomatis* were collected from 244 consecutive women, 21 years of age or less, attending an adolescent health clinic. Positive direct-specimen fluorescein-conjugated monoclonal antibody test for *C trachomatis* results were associated with a past history of chlamydial infection, multiple sexual partners, sexual contact with men with urethritis, nonuse of condoms, metrorrhagia, exocervicitis, mucopurulent endocervical discharge,

abnormal cervical cytologic features, and isolation of *Neisseria gonorrhoeae* from the endocervix. These variables were entered into a discriminant analysis to predict direct-specimen fluorescein-conjugated monoclonal antibody test for *C trachomatis* results. The discriminant function was statistically significant but explained only 17% of between-group variance. Two variables alone, exocervicitis and partners with urethritis, correctly predicted direct-specimen fluorescein-conjugated monoclonal antibody test for *C trachomatis* results in 79% of all cases (negative predictive value 90%; positive predictive value 35%). When routine screening with reliable laboratory tests is not feasible, selective testing or empirical treatment of adolescent women with either risk factor may be cost-effective alternatives.

(AJDC. 1989;143:1437-1442)

Sexually transmitted diseases in adolescent populations are an increasingly urgent public health concern, and illnesses related to *Chlamydia trachomatis* are among the most prevalent, damaging, and costly. Three to four million Americans are infected each year, accounting for annual health expenditures in excess of \$1 billion.¹ As compared with other subpopulations, young women between the ages of 15 to 21 years have the highest prevalence rates² and are especially vulnerable to

the adverse reproductive consequences of infection, including infertility, ectopic pregnancy, and maternal and infant morbidity and mortality.

Two major problems impede an effective public health response through early detection and treatment³: (1) many, if not most, chlamydial endocervical infections escape attention because they are asymptomatic; and (2) mass screening is cumbersome and expensive. In as many as two thirds to three quarters of infected women, objective signs of cervical inflammation are absent.^{4,6} Physical signs, if present, are nonspecific and can be associated with a variety of other sexually transmitted pathogens.⁷ Consequently, the Centers for Disease Control¹ and a National Institute of Allergy and Infectious Diseases fact sheet⁸ have advocated, respectively, selective screening of persons at high risk (en-

compassing a large proportion of sexually active adolescent women) and annual screening of sexually active women under 35 years of age.

There has been considerable discussion regarding the appropriate selection and use of laboratory screening tests. In many laboratories, the "gold standard" tissue culture method is relatively more costly, technically difficult, and slower^{3,9,10} than other diagnostic tests. Yield is influenced by methods of endocervical sampling¹¹ and transport,¹ contamination with viruses or bacteria,¹ the possible presence of endocervical toxins,¹² or other factors. Despite its theoretically absolute sensitivity, actual-use sensitivity in clinics may be as low as 70% to 80%.^{10,13} Antigen detection assays offer relatively speedier, less costly, and less complicated alternatives,¹ but they are generally less accurate than tissue culture methods in research settings. Specificity, sensitivity, and predictive value apparently vary with the risk characteristics of populations, and, in general, they perform best where disease prevalence is high.³

Given the complexities and costs of screening programs, selective testing of women at high risk, based on reliable clinical indicators, has theoretical and practical appeal. A preselection of "at risk" women for specific laboratory diagnosis would improve the predictive value of tests and reduce costs. These considerations are particularly salient to adolescent patients, given their limited financial resources and high risk for disease. Toward this end, investigators have identified a number of potentially useful associations between endocervical *Chlamydia* infection and subjective and objective clinical findings, including clients' ages,^{5,14,15} race,^{5,16,17} socioeco-

Accepted for publication May 1, 1989.

conomic status,⁵ nulliparity,⁵ numbers of sexual partners,^{14,16,18,19} oral contraceptive use,^{5,15} barrier contraception nonuse,^{14,16,20} previous or concurrent history of sexually transmitted diseases,^{2,16,20,21} contact with infected partners,^{2,20} dysuria,^{2,22} vaginal discharge,¹⁸ cervical ectopy,^{19,23} cervical erythema/edema/friability/mucopurulent discharge,^{5,14,15,18,21,24,25} uterine tenderness,^{12,16} and cervical cytologic atypia.^{24,26}

Because these variables are numerous and interrelated, various investigators^{5,14,18,26} have used multivariate statistical techniques to search for a small number of independent, sensitive, specific, and clinically useful predictors of infection. One study¹⁸ used interview data from consecutive clients in a youth clinic, but several others relied on data from a convenience sampling of clinic volunteers²⁶ or from survey completion by clinic attendees,^{5,14} in low prevalence areas (<15%), with combined adult and adolescent populations. So far, results are mixed. This study was intended to advance understanding of clinical indicators of *C trachomatis* endocervical infection in an exclusively adolescent, sexually active population. We hypothesized that demographic data, self-reported sexual behavior, symptoms and signs, and ancillary laboratory studies would be helpful in distinguishing infected from noninfected adolescents.

SUBJECTS

Subjects were 244 consecutive, sexually active women, 21 years of age or less, who required pelvic examination for any reason at a community-based adolescent health facility during a 15-month period in 1986 and 1987. Excluded from the sample were women who were treated for documented or suspected *C trachomatis* infections or who received any antibiotic therapy during the preceding 6 months. Routine screening for chlamydial infection was not available at the site before the study began. Subjects gave written consent to study procedures, in compliance with institutional review board requirements. Only 1 woman refused to participate.

MATERIALS AND METHODS

Clinicians collected and recorded demographic, sexual behavior, and medical data using a semistructured interview format. All variables that were known to be associated^{2,5,14,26} with infection were elicited (see Table 1 for major variables). Clinicians were four physicians and seven nurse practitioners who were skilled in adolescent gynecologic

care. All subjects underwent pelvic examination and had endocervical smears obtained for the direct-specimen fluorescein-conjugated monoclonal antibody test for *C trachomatis* (DFA). Selection of this test was influenced by practical considerations regarding specimen handling and transport at the community clinical site. Other laboratory studies were obtained, as indicated by the reason for the visit or clinicians' judgment.

Clinicians were individually instructed in appropriate data and specimen collection. Endocervical smears for DFA were obtained after sampling for cervical cytologic features and endocervical gonorrhea culture. The exocervix was cleaned with a large cotton swab. A small cotton-tipped swab was inserted into the cervical os and rotated for at least 15 seconds. The swab was rolled onto a glass slide, air dried, fixed with acetone, and transported for processing. Direct immunofluorescent staining with fluorescein-conjugated monoclonal antibody (DSA Laboratory, Panorama City, Calif) was performed according to the manufacturer's instructions. The presence of intact epithelial cells indicated the adequacy of specimen collection. Slides were scored positive if 10 or more distinct, apple-green, fluorescein-stained chlamydial particles were observed. Only one patient required repeated testing because of initially indeterminate results.

To avoid a "training effect" (ie, learning to associate particular clinical findings with infection), clinicians remained blind to the DFA results and were encouraged not to modify their usual approach to examination, diagnosis, and treatment. All subjects with positive DFA results who escaped clinical detection and treatment during their visits received free follow-up care by one of the investigators (S.E.A.). As an added incentive for careful data collection, clinicians were told that their results might be analyzed in relation to other examiners'.

Statistical Methods

Associations between DFA results and demographic/clinical variables were studied by contingency tables, χ^2 , and *t* tests. Normal and ordinal variables were analyzed with the χ^2 test. Interval data were analyzed by *t* tests, after testing the assumption of equal variances. Based on the outcome of univariate analyses, variables were selected for a discriminant analysis to predict DFA results. All tests were performed with SPSS-X software. The designated level of statistical significance was $P < .05$.

RESULTS

Sample Characteristics

Participants were 244 sexually active young women, 13 to 21 years of age

(mean, 17.86 years). Almost all (94%) subjects were white. Eighty-five percent of participants claimed less than \$6000 per year in personal income. Almost all of the others earned less than \$10 000. Reasons for clinic visits were routine annual pelvic examinations (32%), initial family planning examinations (34%), suspected sexually transmitted diseases (19%), or pregnancy (21%). Miscellaneous other problems, primarily menstrual or oral contraceptive complications, accounted for about 10% of visits.

All but two participants had sexual intercourse during the previous year. Almost half of the sample reported only one sexual partner during the year; the remainder were almost equally divided among women with two partners or with three or more partners. Only 2.5% of participants reported having over 10 partners during the year. The most popular forms of birth control were oral contraceptives (used by 41% of the sample) and/or condoms (27%). Thirty percent of participants had never used a reliable contraceptive method.

Laboratory Results

Fifteen percent (36/244) of endocervical smears were positive by DFA. *Neisseria gonorrhoeae* was isolated from 2% (5/228) of endocervical cultures. *Trichomonas vaginalis* was identified in 5% (4/88) of microscopic examinations of vaginal discharge. A preponderance of clue cells (in 17%) and yeast forms (in 27%) were also noted in specimens of vaginal discharge. All syphilis serologic tests were negative. Six percent (13/210) of Papanicolaou smears were abnormal (class IIa or above). Eight percent (19/244) of participants had positive urine or serum pregnancy tests.

Based on clinical findings, examiners correctly predicted 39% (14/36) of positive DFA smears, and all but one of these suspected infections were treated at the initial visit. Of the 208 negative DFA results, 184 (89%) were accurately predicted. The positive and negative predictive value of clinicians' impressions were respectively 37% (14/38) and 89% (184/206).

Univariate Analyses

Comparisons between positive and negative DFA groups are detailed in

‡Variable entered into discriminant analysis.

Table 1 and summarized here. Subjects with positive results were more likely than participants with negative results to report multiple sexual partners during the previous years ($P = .11$) and less likely to report consistent use of condoms ($P = .11$), although these findings did not reach the level of statistical significance ($P = .05$). Statistically significant seasonal differences in infection were noted. Positive DFA results were more prevalent in the fall (23%) and winter (16%) than during the spring (2.8%) and summer (12.5%) months. A greater proportion of positive DFA subjects reported previous chlamydial infection ($P = .06$), metrorrhagia (defined as any intermenstrual bleeding [$P = .0015$]), and sexual partners with urethritis (defined as partner's report of chlamydial urethritis or any symptoms of urethritis [$P = .004$]). Positive DFA results were not associated with age, presenting complaint, or oral contraceptive use (vs any nonuse of oral contraceptives). As indicated in Table 1, some genitourinary tract symptoms were more prevalent among infected women but not to the level of statistical significance.

With respect to physical and laboratory findings, subjects with positive DFA results were more likely to have signs of exocervicitis (defined as cervical erythema and/or edema, and/or friability [$P = .0001$]) and mucopurulent discharge from the cervical os (defined as visualization of yellow mucopurulent discharge on a white swab from the endocervix²¹ [$P = .02$]). *Chlamydia* infections also were associated with the isolation of *N gonorrhoeae* ($P = .004$) and the presence of any Papanicolaou test abnormalities ($P = .03$). No participants had fever or adnexal masses on examination. No significant differences between positive and negative DFA groups were noted with respect to pregnancy test results and microscopic examinations of urine and vaginal discharge.

Discriminant Analysis

A discriminant analysis was used to determine whether positive and negative DFA groups could be differentiated by items from the sexual history, symptoms, signs, and laboratory findings. Nine variables that were associated with DFA results at a level of $P \leq .11$

(Table 1) were entered into the analysis. Seven of these were eligible for inclusion, based on $F > 1$ to enter and a tolerance greater than 0.001 (consistent use of condoms and cervical cytologic results were thus excluded). The discriminant function yielded a canonical correlation of .413, $\Lambda = 0.83$, $df = 7$, and $P = .0000$. The proportion of total variance attributable to between-group differences was 17%. Two variables alone, exocervicitis and contact with a partner with urethritis, accounted for approximately 80% of explained variance. Using a scheme that predicted DFA results to be positive if either variable was present, 79% of all cases were correctly classified (sensitivity, 47% [17/36]; specificity, 85% [176/208]; positive predictive value, 35% [17/49]; and negative predictive value, 90% [176/195]).

COMMENT

This study supports previously described associations between chlamydial endocervicitis and clinical findings in sexually active adolescents, including sexual contact with infected or symptomatic male partners, multiple sexual partners, nonuse of condoms, exocervicitis, abnormal cervical cytologic results, mucopurulent cervical discharge, and endocervical gonorrhea. To our knowledge, the associations of chlamydial disease with metrorrhagia or previous infection have not been described, although they are plausible. Metrorrhagia may herald ascending reproductive tract disease or may be related to friability of the cervix. Adolescents with a history of chlamydial infections may not have received adequate treatment (for various reasons), may have been reinfected by untreated partners, or may have acquired new infections from subsequent partners. In any case, it is disconcerting that 4 of the 12 previously infected young women have ongoing evidence of disease. Although the observation is based on small numbers, it merits further study because of the individual and public health implications of repeated or persistent infection.

Clinical data were better than chance alone in predicting DFA results, but they accounted for only 17% of the total variance between positive and negative DFA groups. Predictive variables were more specific than they were sensitive.

A classification scheme based on exocervicitis and sexual contact with a symptomatic partner better indicated the absence of disease than it did its presence. It is possible that errors in data collection or recording influenced results, though no specific problem areas were noted. False-positive or negative DFA test results might have introduced error into the classification of comparison groups, but the effect was likely to be minor. Stamm³ recently reviewed studies comparing DFA with the enzyme-linked immunosorbent assay tests and tissue culture methods. In populations where disease prevalence exceeded 15%, the median sensitivity and specificity were 90% and 95% for the DFA test, and 89% and 95% for the enzyme-linked immunosorbent assay. As compared with the enzyme-linked immunosorbent assay or tissue culture methods, the DFA test permits assessment of specimen quality.¹ Use of tissue culture for diagnosis might have improved the observed correct classification rate of the predictive model, but it also would have introduced uncertainty regarding adequacy of specimen collection and variability in transport time. Finally, the possibility that some other important predictive variables were missed cannot be excluded. For example, additional information regarding duration of oral contraceptive use, partners' sexual histories, or cumulative years of sexual intercourse may have been helpful.

The performance of the discriminant function was less than ideal but was comparable with results from other populations (Table 2). Among the various studies, gonorrhea, cervicitis, and sexual contact with an infected partner have consistently emerged as independently predictive of chlamydial infection. However, individual clinical findings (ie, cervical erythema, vaginal symptoms, or discharge) accounted for only 3.2% to 9.1% of variance between infected and noninfected adolescent women studied by Fisher et al.¹⁸ Schachter and colleagues⁵ found that the presence of one of several risk factors (gonorrhea, endocervicitis, and sterile urinary tract infection) identified only 30 chlamydial infections in their sample, with an overall positive predictive value of 36%. Harrison et al²⁶ re-

ported that two variables, cervicitis and nonuse of barrier contraceptive methods, had 28% positive and 98.4% negative values in predicting tissue culture results. They recommended selective laboratory testing or treatment for women with either finding.

Using a somewhat different approach, Handsfield and colleagues¹⁴ discovered five factors (including age <25 years and nonuse of condoms) that were predictive of infection. Any combination of two resulted in a greater than 4.7% risk of infection, and they recommended selective testing of women with more than one risk factor. This method maximizes the sensitivity (90%) of clinical prediction at the expense of specificity (63%). Accordingly, a projected 65% of their own sample would have been tested, and 90% of infections would have been detected. The advice of Harrison et al²⁰ and Handsfield et al for selective screening might be limited in an adolescent population, such as our own, where less than 14% of clients used condoms consistently, and nearly all would meet criteria for testing.

Had our model been used to pre-screen clients for laboratory studies or empirical treatment, 20% (49/244) of the sample would have been identified as at risk for disease. Overall, 79% of all participants would have been correctly classified by the two variables, but over half of the infections (19/36) would have been unsuspected. However, if the model were applied to a lower prevalence population such as that of Harrison et al²⁰ (8%), its negative predictive value would rise sharply to 95%, and fewer infections would be missed.

CONCLUSION

Responding to the problem of asymptomatic infection, authorities have advised routine screening. However, young patients often are unable to assume the costs, and the need for confidentiality limits billing of parents or third-party payers. Faced with a financial predicament, clinics and practitioners may select the least expensive screening tests, test only "high risk" clients, or simply treat suspected infections (with or without treatment of contacts). Clinicians should be advised of the limitations of these practices.

Without the benefit of specific labora-

tory diagnosis, clinicians who participated in this investigation correctly classified 81% of the sample and detected 39% (14/36) of infections. Nine percent (18/208) of subjects with negative DFA results and their partners were suspected to have infection and were treated. By comparison, selective laboratory testing of patients with cervicitis or with presumptively infected male partners would have improved case detection and possibly reduced overtreatment. This approach might be cost-effective in low-prevalence populations. Schachter¹⁰ estimated that 1 in 10 infected women develops salpingitis, at a cost of \$2000 in direct medical expenses. Thus, in a population of 1000 adolescent women where disease prevalence is 8%, the cost of selective screening by our method would equal the price of 176 tests and four cases of salpingitis. According to this simple analysis, less than \$9.71 per person should be spent for cost-effective screening. By the same reasoning, routine testing becomes even more valuable as disease prevalence increases. For example, when 15% of women are infected, the cost of salpingitis would merit per capita expenditures up to \$19.95. Ultimately,

other costs such as the price of infertility or neonatal infection must be factored into the equation.

An alternative cost-saving approach is to treat empirically persons with suspected infections and to test all others. In the study population, this would amount to a 20% reduction in laboratory expenses for screening, and, theoretically, no infections would be missed. However, 15% (32/208) of women with negative DFA results and their partners would have received treatment. Beyond the possible problems associated with medication side effects and misdiagnosis, absence of laboratory confirmation of disease may adversely affect patient compliance with treatment and contact notification.

In conclusion, a number of clinical findings are associated with DFA results in a population of sexually active adolescent women. These findings can be used to discriminate positive and negative DFA groups but explain only 17% of the variance. The specificity of the proposed predictive model exceeds its sensitivity. In adolescent populations where routine screening for *C trachomatis* is not feasible, judicious use of selective testing or treatment of women

with exocervicitis or presumptively infected partners may be cost-effective alternatives.

High Prevalence Rate of Human Papillomavirus Infection and Association With Abnormal Papanicolaou Smears in Sexually Active Adolescents

Walter D. Rosenfeld, MD; Sten H. Vermund, MD, MSc; Sally J. Wentz; Robert D. Burk, MD

• Human papillomaviruses (HPVs) are associated with neoplastic and malignant lesions of the uterine cervix. Cervical neoplasia is associated with onset of sexual activity at an early age. Therefore, this study sought to define the prevalence rates of HPV infection and cytologic abnormalities in adolescents. Sexually active females 13 to 21 years of age undergoing routine cervical cytologic screening were evaluated in the adolescent clinic of an urban hospital. Cells collected by cervicovaginal lavage from 249 subjects were analyzed for HPV DNA by Southern blot hybridization with probes for HPV types 6/11, 16, and 18. The HPV DNA was detected in 95 (38.2%) of 249 patients. Teenagers between the ages of 13 and 18 years with multiple lifetime sexual partners were at higher risk for HPV infection (38/71 [54%]) compared with patients of the same age who had only a single partner (25/74 or [34%]). Twenty (8.3%) of 241 patients had abnormal Papanicolaou smears with atypia, koilocytosis, or low-grade cervical intraepithelial neoplasia. Cytologic abnormalities were detected in 16 (17%) of 94 adolescents with HPV present, but in only 4 (2.7%) of 147 of the uninfected patients. Thus, HPV emerged as a common pathogen in female adolescents, and infected patients are at increased risk for cervical epithelial abnormalities.

Human papillomaviruses (HPVs) have been implicated by molecular hybridization studies in the pathogenesis of cervical intraepithelial neoplasia¹⁻⁶ and invasive cancer of the uterine cervix.⁶⁻⁸ Most research in this area has focused on adult women, since invasive cervical cancer rarely occurs before 30 years of age. However, coitus^{9,10} and pregnancy at a young age¹¹ are risk factors for cervical cancer that relate primarily to adolescents.

While many studies have attempted to explore the importance of HPV infection in adult women, including those without cervical lesions,¹² little information has specifically concerned adolescents with limited years of sexual exposure.¹³ The present study was designed to determine the prevalence rate of and potential risk factors for cervical and vaginal HPV infection in sexually active female adolescents. Papanicolaou (Pap) smears were obtained to determine the relationship between HPV infection and cervical abnormalities. Demographic and behavioral information was used to compare the descriptive epidemiologic characteristics of HPV-positive and HPV-negative individuals.

PATIENTS AND METHODS

Patient Selection

Sexually active female adolescents who were due to have a routine annual Pap smear or in whom cervical cytologic screening was otherwise clinically indicated (eg, history of abnormal vaginal bleeding or possible cervicitis) were eligible for inclusion in the study. The patients, 13 to 21 years of age, were seeking gynecologic care at the Adolescent Ambulatory Service of the Montefiore Medical Center, Bronx, NY, from February 1986 through April 1988. The protocol was ap-

proved by the Institutional Review Board and Research Committee of the medical center.

Written informed consent was obtained from 264 of 273 eligible patients. In 4 patients, specimens were inadequate for HPV determination, and 11 others did not have cervicovaginal lavage on the day of their visit. Thus, the study group consisted of a total of 249 patients who had HPV assessment. Eight patients without Pap smears were excluded from the analyses concerned with cytologic findings. Characteristics of the study subjects are shown in Table 1. The sample subjects were 42% (105) black, 42% (104) Hispanic, 14% (34) white, and 2% (4) from other ethnic backgrounds.

The patients enrolled in the study were seeking gynecologic care on the day of the visit for a variety of reasons that included contraception (45%); problems likely to be related to a sexually transmitted disease (STD) or urinary tract infection, such as genital lesion (excluding warts), dysuria, vaginal discharge (31%); menstrual disorders or abdominal pain (18%); diagnosis of pregnancy or follow-up care after an abortion (9%); and genital warts (2%). One patient had been referred for an abnormal Pap smear.

Clinical Examination, Specimen Collection, and Cytologic Evaluation

Clinical and sociodemographic information was collected through patient interviews and a review of the medical records. Assessment of current or past pregnancy was made by clinical interview and chart review. A serum β -subunit of human chorionic gonadotropin assay was used to confirm pregnancy when either the physical examination or histology suggested pregnancy.

The Pap smears were obtained with a cotton swab from the endocervical canal and by rotating a plastic spatula 360° over the exocervical surface. Smears were evaluated by the cytopathologists at the Montefiore Medical Center who were unaware of patient HPV status. A Pap smear was considered

*HPV represents human papillomavirus. No significant differences occurred between infected and uninfected subjects.

†Gynecologic age was chronological age minus age at menarche.

‡Three patients reported first coitus during sexual abuse before the age of 12 years.

be abnormal when atypia, koilocytosis, or epithelial cells suspicious for cervical intra-epithelial neoplasia were present.

Cultures for *Neisseria gonorrhoeae* were obtained in 225 (90.4%) of 249 patients, using modified Thayer-Martin medium, excluding those with a recent negative culture. Testing for *Chlamydia trachomatis* was performed on 138 (55.4%) of 249 patients with either the direct fluorescent monoclonal antibody test or a McCoy cell culture using confluent monolayers on a coverslip.¹⁴ During the first 16 months of the study, tests for *C trachomatis* were performed on 96 patients with identifiable risk factors for this infection, whereas during the latter part of the study, an evaluation for chlamydial infection became a part of the routine clinical assessment.

Cervicovaginal lavage was used to obtain exfoliated cervical cells for molecular detection of HPV DNA.¹⁵ The cervix was lavaged with 10 mL of 0.9% saline solution using a syringe fitted with a 14-gauge Teflon catheter. The fluid in the posterior fornix was aspirated and transferred to a centrifugation tube containing 1 mL of 0.5 mol/L edetic acid and stored at 4°C.

Detection of HPV DNA by Southern Blot Analysis

The methods used in this study were previously described.¹⁵ Briefly, DNA was extracted from the cervicovaginal cell pellet and purified by phenol chloroform extraction. Five to ten micrograms of DNA was digested with *Pst* I. Southern blot was performed using gel-isolated HPV DNA probes labeled with phosphorus 32 from HPV types 6/11, 16, and 18. The HPV DNA type was determined by a combination of the *Pst* I restriction pattern and the hybridization specificity with different HPV DNA-type probes. The DNA hybridization results were determined without the knowledge of other study results or individual patient information.

Data Analysis

Epidemiologic, clinical, and laboratory data were coded and analyzed with commer-

cial software statistics packages. Frequency distributions, cross tabulations, and descriptive summary statistics were calculated. The χ^2 test (with the Yates' continuity correction for 2×2 tables), comparisons of two means, comparisons of two proportions, and Fisher's Exact Test were used for comparing characteristics of HPV-positive and HPV-negative subjects.¹⁶ Mantel-Haenszel summary odds ratios (OR_{MH}) were calculated for the relationship between HPV infection and patient age to control for the number of sexual partners.¹⁷

RESULTS

The prevalence rate of HPV infection in the 249 patients was 38.2%. An example of HPV DNA detection and typing by restriction analysis and molecular hybridization is shown in Fig 1. Samples 2, 4, 5, 7, 9, 11, 13, 15, 16, and 18 contain HIV DNAs and demonstrate the marked heterogeneity of types detected. In the 95 subjects with infection, HPV 6 or HPV 11 was found in 6 patients (6%), HPV 16 was found in 15 patients (16%), HPV 18 in 14 individuals (15%), and HPV DNA that was partially homologous with HPV 16 was observed in 7 patients (7%). Sixty-four (67%) of the 95 infected subjects had an HPV uncharacteristic for the above types, termed a "related" HPV. Eleven (12%) of the patients had two different HPV types present.

Of the various reasons that patients sought care on the day of their visit, only the presence of condylomata acuminata was more likely to be associated with the presence of HPV ($\chi^2=6.26$, $P=.018$, excluding patients with condylomata acuminata). The percentages of HPV-positive patients within each of the presenting complaint groupings are shown in Fig 2.

Unexpectedly, for the group the

Fig 1.—Detection of human papillomavirus (HPV) DNA by *Pst* I restriction and Southern blot analysis using a mixed probe of HPV types 11, 16, and 18. Sample DNAs are indicated by small numbers 1 through 22. The HPV DNA types 6, 11, 16, and 18 (20 ng) were digested with *Pst* I and served as the positive controls as indicated in the first and last lanes of each panel. Lanes designated M (size marker) contain phosphorous 32-end-labeled lambda-DNA-*Hind*III fragments.

number of lifetime sexual partners did not reach a statistically significant association with HPV infection: 61 (66%) of 92 of the HPV-positive patients had had more than one lifetime partner, while 81 (54%) of the 151 uninfected patients had more than one partner ($P=.07$). However, the younger patients, 13 to 18 years of age, were nearly twice as likely to be infected with HPV than those 19 to 21 years old, a finding that was mainly attributable to patients with more than one lifetime sexual partner (Table 2)

Fig 2.—Percentages of patients positive for human papillomavirus (HPV) among the total number of patients within each chief complaint grouping. The number of patients within each group is shown in parentheses. The sexually transmitted disease group does not include patients with genital warts.

Table 2.—Proportion of Patients Infected With Human Papillomavirus (HPV) According to Number of Sexual Partners by Chronological Age*

Chronological Age, y	HPV-Positive Patients, No. (%)		Total
	Single Partner	Multiple Partners	
13-15	5/15 (33)	4/6 (67)	9/21 (43)
16-18	20/59 (34)	34/65 (52)	54/124 (44)
19-21	9/33 (27)	23/71 (32)	32/104 (31)

*Mantel-Haenszel summary odds ratio = 1.9; 95% confidence interval = 1.1 to 3.4.

(OR_{MH} = 1.9; 95% confidence interval [CI] = 1.1 to 3.4).

Chlamydia trachomatis was found in 24 (17%) of 138 persons screened. *Neisseria gonorrhoeae* was found in 5 (2%) of 225 individuals tested. *Chlamydia trachomatis* was found in 18 (18.8%) of 96 patients in the selective first part of the study compared with 6 (14.3%) of 42 patients seen in the latter part of the study when testing was used more routinely (this finding was not statistically significant). Among persons with either gonococcal or chlamydial infection, 8 (30%) of 27 were also infected with HPV, while among persons without *N. gonorrhoeae* or *C. trachomatis*, 46 (41%) of 111 were infected with HPV ($P = .4$).

Twenty (8.3%) of 241 patients had abnormal Pap smears. Six patients dem-

onstrated cytologic changes that were suspicious for low-grade cervical intraepithelial neoplasia, 2 had koilocytosis or other findings suggestive of condyloma, and 6 had smears in which low-grade cervical intraepithelial neoplasia could not be distinguished from koilocytosis. The remaining 6 patients had cellular atypia that was not specific. Cervical cytologic abnormalities were detected in 16 (17%) of 94 adolescents with HPV present, but in only 4 (2.7%) of 147 of the uninfected patients (OR = 7.3; 95% CI = 2.4 to 22.7). When the patients with atypia that was not specific were excluded from the analysis, the strongly positive relationship between HPV infection and abnormal Pap smears remained (OR = 11.0; 95% CI = 2.4 to 50.4). No relationship was

found between the patient's age or number of sexual partners and the likelihood of having an abnormal Pap smear.

Abnormal Pap smears were found in 2 (40%) of 5 patients with HPV type 6/11 present, in 3 (20%) of 15 with type 16, in 2 (14%) of 14 with type 18, in 1 (14%) of 7 with a 16-related type, and in 11 of 64 (17%) with other related HPV types (Fig 3). The HPV type 6/11 was more common among patients with condyloma acuminatum (3 [30%] of 10) than in patients without warts present (3 [3%] of 96, $P = .01$). Eight patients had condylomata acuminata of the vulva or vagina on physical examination, all of whom had a positive result for HPV on their cervicovaginal lavage specimen. Three (37.5%) of these 8 subjects had an abnormal Pap smear, while 17 (7.4%) of 231 of those without condylomata present had an abnormal Pap smear ($P < .05$).

Patients infected with HPV were more likely to have a history of pregnancy, although this association did not reach statistical significance. Forty-two (44.7%) of 94 adolescents who had been pregnant at least once had HPV infection, whereas only 50 (33.6%) of 149 of the nulligravida patients had HPV DNA detected ($P = .1$).

COMMENT

Urban female adolescents in the United States have a mean age of first coitus of 16 years,¹⁸ and as many as 4% of sexually active teenagers and young adults have cervical intraepithelial neoplastic lesions.^{19,20} In addition, more than 1 million pregnancies occur annually among teenagers in the United States.²¹ Additional risk factors for cervical cancer common among some young people include having multiple sexual partners, having a high-risk partner, and cigarette smoking.^{11,22}

Furthermore, sexually active adolescents are at high risk for STDs. *Neisseria gonorrhoeae* has been found in 1% to 18%²³⁻²⁵ and *C. trachomatis* in 14% to 26%²⁶⁻²⁹ of adolescents. A trend over the past 20 years toward an increased frequency of condyloma acuminatum has been reported in all age groups, including some of the highest rates among adolescents.³⁰

The strikingly high prevalence rate of 38% indicates that HPV may be the

Fig 3. — Percentage of each human papillomavirus (HPV) DNA type among the 95 patients with HPV infection (11 patients had two HPV DNA types); for each HPV DNA type, the percentage of patients with an abnormal Papanicolaou (Pap) smear is listed. N indicates the number of patients with each HPV DNA type.

most common STD among female adolescents seeking care within an urban teaching hospital clinic. The investigation of other populations of adolescents will be required to determine whether this virus is as common among diverse groups of sexually active adolescents. The methods used here, including the cervicovaginal lavage for cell harvesting³¹ and Southern blot molecular hybridization for viral DNA detection, probably account for the higher HPV prevalence rate than has been reported by other investigators.¹⁸ (Only 1.6% of the lavage specimens provided insufficient cell quantity for Southern blot experiments in our study.)

Some of the sociodemographic and behavioral characteristics of our patients differ from other groups of young people. Yet, the adolescents in the present study were seeking care for the full range of gynecologic and family-planning issues. Less than one third of the patients had a chief complaint directly related to an STD. Moreover, those patients whose visit was prompted by a symptom possibly related to an STD were not more likely to be HPV-positive. The rates we observed for gonorrhea and *Chlamydia* are consistent with published studies in comparable

populations of young people.^{23,26,28} Furthermore, the mean age of menarche and frequency of previous pregnancy among our patients were similar to reports of other populations, suggesting that our results indeed may be applicable to other urban youth.^{18,32}

The high-risk status for STDs associated with adolescence is likely to be related to a combination of behavioral, psychosocial, and biological factors that also have a bearing on infection with HPV and the development of cervical neoplasia. Sexual experimentation, poor use of barrier methods of contraception, and inadequate use of health care services because of fears regarding confidentiality are common in adolescence.³³ The transformation zone of the cervix, the area where the columnar cells undergo metaplastic transformation, is larger during adolescence than later in life. This zone is not only more susceptible to infection with sexually transmitted pathogens but is also known to be the area from which most cervical cancers originate.³⁴ The strong association observed in our patients between HPV infection and cytologic abnormalities is consistent with findings from multiple studies of adult women.

It is not surprising that the older pa-

tients in the study (those at least 19 years of age) had been sexually active for more years and reported having more lifetime sexual partners. However, of interest is the finding that young age was associated with HPV infection in patients who had more than one lifetime sexual partner. One implication from this observation is that young female adolescents (but not necessarily older adolescents) who have had multiple sexual partners should be considered at higher risk for STDs.

The age-dependent association of number of sexual partners with HPV was not found for chlamydial infection or gonorrhea. While *C trachomatis* and *N gonorrhoeae* are certainly also transmitted through sexual contact, they are more likely than HPV to produce symptoms that prompt a medical visit and effective treatment. An HPV infection is typically asymptomatic (only 8% of the HPV-positive patients had condyloma acuminatum) and, in some patients, may persist over time.³⁵ Even when infection with HPV is recognized, treatment modalities are often unsuccessful. Our patients' knowledge regarding a history of STDs was not found to be reliable (data not shown). Perhaps if such data were available, similar associations might be found between ever having had *C trachomatis* or *N gonorrhoeae* and the presence of HPV, as well as with their number of lifetime sexual partners.

A number of considerations may have contributed to the fact that we did not detect a statistically significant association between HPV infection and previously reported risk factors for cervical cancer in the population as a whole. It may be assumed that both HPV-infected and uninfected young women share certain features of adolescence within an urban environment. Therefore, differences in the behavioral characteristics between the infected and uninfected groups may be too small to reach statistical significance with the present sample size. Another possibility is that many of the male partners of our patients may have had numerous sexual contacts. In that case, the young women who reported having had only a single lifetime partner, but whose partner had had numerous sexual contacts, might nonetheless have had the same degree

of exposure to sexually transmitted pathogens as the patients who reported having had many partners.

The presence of HPV may serve both as a sensitive indicator of sexual exposure and of risk for cervical abnormalities. Also, since concurrent infection with multiple STDs is common, the discovery of one STD in a patient may serve as a warning to the likely presence of others. This is of particular concern, given current apprehension regarding the risk for acquired immunodeficiency syndrome in the adolescent population.³⁶

The high prevalence rate of HPV observed in our study is distressing. Since

HPV infection is usually asymptomatic, identification and treatment of contacts are more difficult. Such HPV-infected adolescents are at far higher risk of cervical cytologic abnormalities than those without this virus present. It remains uncertain whether these HPV-infected persons are at substantially higher risk for development of cervical dysplasia and invasive cancer later in life. Cofactors such as cigarette smoking, other STDs, and lack of access to health care may be important. Prospective follow-up of both infected and uninfected adolescents, both with and without cytologic abnormalities, should contribute to our understanding of the natural his-

tory of HPV infection in young people.

This study was supported in part by a grant from the Brookdale Foundation, New York, NY; Clinical Investigator Award K08 CA-00983 (Dr Burk) from the National Cancer Institute, Bethesda, Md; the Michigan State University Biomedical Student Research Program, East Lansing; and the Health Research Training Program of the New York City (NY) Department of Health (Ms Wentz).

Human papillomavirus types 6, 11, 16, and 18 cloned in a plasmid vector (pBR322) were kindly provided by Lutz Gissmann, PhD, and Harald zur Hausen, MD, Heidelberg, West Germany.

S. Kenneth Schonberg, MD, Leopold G. Koss, MD, and Anna Kadish, MD, reviewed the manuscript. Cervical cytologic specimens were analyzed by Klaus Schreiber, MD, and associates. Susan Coupey, MD, Diane Ritter, MD, Dottie Mitchell, Sheila MacLeod, MPH, Elaine Russell, Rosalind Carter, Wendy Fried, Shirley Saed, and Carol Spitzer, MS, contributed to the research.

Study of Virus Isolation From Pharyngeal Swabs in Children With Varicella

Takao Ozaki, MD; Yoshiharu Matsui, MD; Yoshizo Asano, MD;
Toshiomi Okuno, MD; Koichi Yamanishi, MD; Michiaki Takahashi, MD

• We performed virus isolations from the pharyngeal swabs in 117 children with varicella who were aged from 22 days to 15 years and 70 healthy children who were aged from 3 months to 15 years, by using human embryonic lung cell cultures. Viral isolates were confirmed by an indirect immunofluorescence method or by neutralization with well-characterized antibodies. Five varicella-zoster virus isolates (4.3%), 23 cytomegalovirus isolates (19.7%), five herpes simplex virus isolates (4.3%), and one respiratory syncytial virus isolate (0.9%) were found in the patients with varicella. Ten cytomegalovirus isolates (14.3%), two herpes simplex virus isolates (2.9%), one respiratory syncytial virus isolate (1.4%), and one poliovirus isolate (1.4%) were found in the swabs of the healthy control children. The varicella-zoster virus isolation rate from the pharyngeal swabs in children with varicella was low as compared with the rate from those pharyngeal swabs in the children with cytomegalovirus and herpes simplex virus. No varicella-zoster virus isolates could be found in the swabbed materials after filtration (0.45 μ m). On the other hand, cytomegalovirus and herpes simplex virus could be isolated from the filtrated swabs, as well as from the unfiltered swabs. The method of testing by filtration could have affected the results. (AJDC. 1989;143:1448-1450)

Varicella, caused by primary infection with varicella-zoster virus (VZV), is a common and highly contagious disease of childhood. Varicella-zoster virus is assumed to spread by

droplet nuclei or air droplets, because airborne transmission of varicella in hospitals has been demonstrated.^{1,2} We report the results of our attempts to isolate VZV from the pharynx of patients with varicella; the pharynx is considered to be the main source of infection by the end of the incubation period and during the first days of the exanthem.

SUBJECTS AND METHODS

This study was conducted at the pediatric outpatient clinic of Showa Hospital, Kohnan, Japan. Children in this study comprised patients with varicella and healthy children as controls. One hundred seventeen children with varicella, who had no known underlying diseases and were not receiving immunosuppressive therapy, were aged from 22 days to 15 years (mean age \pm SD, 3.62 ± 2.90 years). Five of these children had varicella during the incubation period. The second group included 70 healthy children who were aged 3 months to 15 years (mean age \pm SD, 4.66 ± 4.48 years). After the project was explained, consent was obtained from the parents.

Pharyngeal swabs were taken from 187 children in both groups in a single instance. The collecting medium was Eagle's minimal essential medium with 10% fetal calf serum that contained some antibiotics (streptomycin, 100 mg/L; penicillin G, 100 000 U/L; ampicillin, 250 mg/L; and amphotericin B, 12.5 mg/L).

The scheme of virus isolation is shown in Fig 1. Human embryonic lung cells between 7 and 20 passage levels were used for the virus isolation study. All swabbed materials, after 4 hours of incubation, at the most, in the collecting medium at 4°C, were directly inoculated onto cell cultures (method A). At the same time, one-half volume of 67 swabbed materials obtained from the patients with varicella and of 37 swabbed materials obtained from the healthy children were inoculated after filtration with a 0.45- μ m filter unit (Millipore, Swinnox-HA, Bedford, Mass) (method B). The cultures were observed daily, and even if no cytopathic effect was observed, the cells were treated with

trypsin and suspended in a maintenance medium. The cell suspension was then mixed with a newly prepared human embryonic lung cell suspension in a growth medium. Observation was continued for a further period of about 3 weeks. When no cytopathic effect was detected at the end of the observation period, the virus isolation was considered to be negative.

Viral isolates were primarily identified by a characteristic cytopathic effect. An indirect immunofluorescence assay was then used for the identification of VZV, cytomegalovirus (CMV), and herpes simplex virus (HSV). The monoclonal antibody, highly specific for VZV, and the polyclonal antibody to HSV were made in the laboratory of one of us (M.T.). The procedures for the preparation of the monoclonal antibody to VZV have been described previously in detail.³ The monoclonal antibodies, commercially available to CMV (Dakopatts, Glostrup, Denmark) and to HSV type 1 or HSV type 2 (Syva, Palo Alto, Calif), also were used. A neutralization test was done for the identification of respiratory syncytial virus and poliovirus with standard, commercially available antisera (Seiken, Tokyo, Japan). In addition, a T-marker test was done against an isolate of poliovirus.

To control the quality of our isolation techniques, the isolation attempts were performed from the vesicular fluid during the first 3 days of varicella. The positive rate of VZV isolation was more than 90% by method A (data not shown).

The frequency data of virus isolation in the two groups were compared by the χ^2 test.

RESULTS

Figure 2 shows that 5 VZV isolates (4.3%), 23 CMV isolates (19.7%), 5 HSV isolates (4.3%), and 1 respiratory syncytial virus isolate (0.9%) were found in the pharyngeal swabs obtained from 117 children with varicella. The cytopathic effect appeared within 7 days in all 5 HSV isolates, but in 2 of the 5 VZV isolates and in 9 of the 23 the CMV isolates, we needed the second subculture for the cytopathic effect appearance. No virus could be isolated from

Table 1 demonstrates a comparative study of the incidence of the virus isolation from the pharyngeal swabs between patients with varicella and healthy control children. Ten CMV isolates (14.3%), 2 HSV isolates (2.9%), 1 respiratory syncytial virus isolate (1.4%), and 1 poliovirus isolate (1.4%) were obtained from the group of healthy children. With regard to the virus isolation frequency, there was no significant difference between the two groups, except for VZV. The CMV and HSV infections were inapparent in all the CMV- and HSV-positive children in both groups, and the clinical features of varicella did not seem to be explicitly influenced by CMV and HSV. The 7 HSV isolates were all confirmed to be type 1 by the test of neutralization. A child who had been inoculated with a live oral poliovirus vaccine 8 days previously yielded a polio vaccine virus type 2 in the pharynx.

One hundred four swabs in both groups were inoculated onto the cell cultures by two methods at the same time, directly (method A) and after filtration (method B). This comparative study of virus isolation between the filtrated and unfiltrated swabs is shown in Table 2. No VZV could be isolated from the swabs after filtration. In contrast, CMV (93.8%) and HSV (100%) could be isolated from the filtrated swabs, as well as from the unfiltrated swabs.

COMMENT

Although VZV can be readily isolated from the vesicular fluid obtained within the first 3 days of the rash, it is difficult to isolate VZV from the other portions. Recently, we have demonstrated viremia in children with varicella who had no underlying diseases, by using a sensitive human embryonic lung cell culture

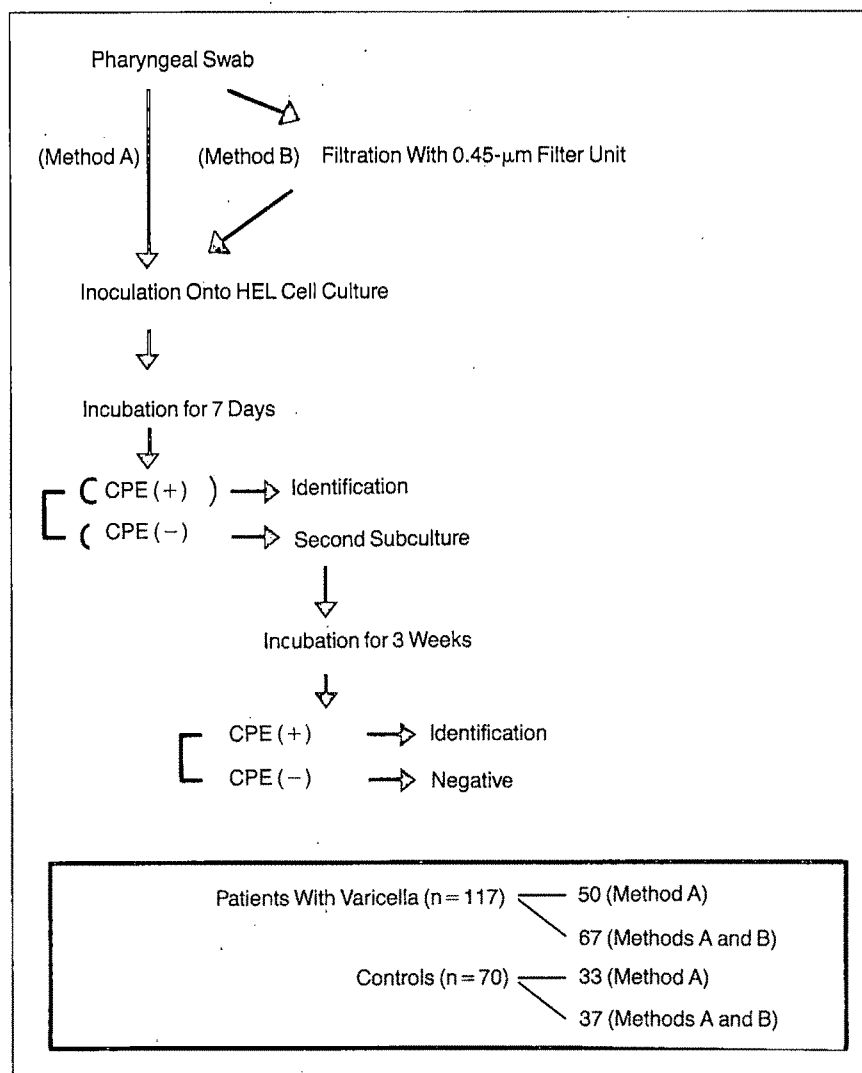

Fig 1. —Scheme of virus isolation. HEL indicates human embryonic lung; CPE, cytopathic effect.

Fig 2.—Virus isolation from patients with varicella. VZV indicates varicella-zoster virus; CMV, cytomegalovirus; HSV, herpes simplex virus; and RSV, respiratory syncytial virus.

Table 1.—Incidence of Virus Isolation*

	Incidence (%)	
	Patients With Varicella (n = 117)	Controls (n = 70)
VZV	5/117 (4.3)	0/70 (0)
CMV†	23/117 (19.7)	10/70 (14.3)
HSV†	5/117 (4.3)	2/70 (2.9)
RSV†	1/117 (0.9)	1/70 (1.4)
Poliovirus†	0/117 (0)	1/70 (1.4)‡

*VZV indicates varicella-zoster virus; CMV, cytomegalovirus; HSV, herpes simplex virus; and RSV, respiratory syncytial virus.

†Isolation rate was not significantly different by the χ^2 test.

‡The isolated strain was type 2 and the vaccine type.

Table 2.—Comparative Study of Virus Isolation Between Filtrated and Unfiltrated Swabs*

Virus	Filtrated/Unfiltrated Swab Result
VZV (n = 3)	Filtration (+)/filtration (−) = 0/3
CMV (n = 16)	Filtration (+)/filtration (−) = 15/16
HSV (n = 3)	Filtration (+)/filtration (−) = 3/3

*VZV indicates varicella-zoster virus; CMV, cytomegalovirus; HSV, herpes simplex virus.

technique.^{4,6} The viremia has been shown not only during the first few days of varicella but also in the incubation period.⁶

As far as we know, VZV isolation from the pharyngeal area has been reported in a small number of cases. Gold,⁷ Cesario et al,⁸ and Myers⁹ reported one case each. Trlifajova et al¹⁰ reported five VZV strains that were isolated, three from nasal and two from pharyngeal swabs, but their patients with varicella, from whom swabbed materials were taken, had various forms of congenital defects (Down syndrome, alkaptonuria, amaurosis, epilepsy, oligophrenia, hydanoinate syndrome, retinitis pigmentosa, etc), except for two normal individuals. In the present study, we found five VZV isolates on the pharyngeal mucosa at the time of the developing exanthem in normal children with varicella. Nelson and St Geme¹¹ and Trlifajova et al¹⁰ did not isolate VZV from 8 and 57 pharyngeal swabs, respectively, during the preeruption period, and in our study, we also did not isolate VZV similarly from the children during the incubation period.

In our study, 23 CMV isolates (19.7%) were found in the children with varicella, and 10 CMV isolates (14.3%) were found in the healthy control children. Salivary shedding of CMV was observed commonly, as well as urinary shedding. The high incidence of excre-

tion from the pharyngeal swabs in infants diminishes accordingly as the age increases.¹²⁻¹⁵ The positive rates of CMV from the pharyngeal swabs, 14.3% in healthy children and 19.7% in children with varicella, were almost the same as that found in the reports of many researchers.^{10,12-16} As CMV- and HSV-positive isolation rates did not differ significantly between patients with varicella and healthy control children, no evidence was demonstrated that the VZV infection altered the immunologic state of the host and might increase their positive isolation rates.

Epidemiologic data, including an experiment of VZV infection to the common marmoset,¹⁷ suggest that a phase of respiratory tract repose exists. However, the incidence of recovering VZV from the pharynx was low, and the VZV isolates could not be found in the swabs after filtration. The results of our study indicated that a small number of infective VZV particles existed on the pharynx of children with varicella, and that the method of testing by filtration may affect the isolation of VZV. Why the virus is easily isolated from vesicular lesions and elusive in the pharynx poses some interesting questions. It may be possible that the impressive communicability of varicella results simply from the extensive airborne and contact dissemination of the more thermostable virus from the cutaneous vesicles. How-

ever, these reflections are inconsistent with an epidemiologic factor that a patient with varicella may transmit the disease to other susceptible persons from approximately 1 day before the onset of the rash. To confirm those reflections and to resolve this paradox, we will continue with a further isolation study of VZV by using a more sensitive technique, eg, DNA hybridization.

Transmission of Chickenpox in a School Setting Prior to the Observed Exanthem

Philip A. Brunell, MD

• An epidemic of chickenpox in a class is described. Four children were able to transmit infection prior to the time their rash was observed by their parents. A fifth child was known to have attended school while he had localized varicelliform lesions that were present for 2 days prior to the appearance of the generalized exanthem. It cannot be ascertained whether some of the other children may have had similar lesions that were not observed at the time they attended school. The first classroom case was observed prospectively so that the time of rash was fairly well established. Although he apparently transmitted infection prior to the onset of rash, virus could not be isolated from the respiratory secretion of this child on the day he presumably infected his classmate. Virus was not found in his respiratory secretions or those obtained from his two siblings before or after the onset of rash, although it was recovered from vesicular fluid.

(AJDC. 1989;143:1451-1452)

It is generally assumed that patients with chickenpox are contagious prior to the onset of rash.¹ If these patients are indeed contagious at this time, they must spread varicella-zoster virus from a site other than their skin lesions. It is known that many viral infections are spread via the respiratory tract and that virus can be readily demonstrated in the respiratory secretions of patients with these infections.^{2,3} In spite of the presence of lesions in the mouths of some patients with varicella, isolation of varicella-zoster virus from pharyngeal secretions has been reported only rarely.^{4,5} Systematic attempts by others

either have failed⁶ or met with limited success.^{7,8} We present epidemiological evidence that indicates that patients with chickenpox may be contagious prior to the time their rash is observed. The respiratory tract could not be established as the source of infecting virus as varicella-zoster could not be detected in respiratory secretions of patients with chickenpox.

EPIDEMIOLOGICAL OBSERVATIONS

The index case was a physician who became ill with chickenpox. Onset of the typical varicelliform rash occurred in his three children 13, 14, and 14 days after the lesions were observed on their father's skin. The children were examined thoroughly and specimens of nasal and pharyngeal secretions were obtained daily from the 10th day after exposure to the second day following the rash. The oldest of the three children was first noted to have a varicelliform rash at noon on a school holiday; the rash was not present that morning when he was examined at the time of specimen collection or the previous evening. Consequently, it was assumed that no skin lesions were present the previous day when he last attended school. A postcard inquiry at the time of onset of the first classroom case indicated that (1) none of his classmates had chickenpox previously during the school year, (2) none of his classmates had contact with others with chickenpox in the community, and (3) seven classmates had not had chickenpox.

Chickenpox occurred in five of seven contacts at approximately 2-week intervals; ie, at 17, 28, 43, 57, and 57 days after exposure. In four of the five contact cases, including the physician's child, the rash was discovered while the children were home. In each of these instances, the parents denied that their children had attended school when the rash was present. The mother whose child had the onset of chickenpox at 43 days acknowledged that her son had attended school for 2 days while lesions were present on his neck. Extracurricular exposure was denied in all cases. All five susceptible sibling contacts of

the classroom cases developed chickenpox 2 to 3 weeks after the household exposures.

VIRAL STUDIES

Specimens of vesicular fluid were collected on the second or third day of the rash with capillary pipettes and taken immediately to the laboratory where they were inoculated into cultures of human embryonic lung fibroblasts. Specimens of pharyngeal or nasal secretions were collected with dry cotton swabs. These swabs were placed immediately into screw-capped tubes containing 1 mL of partially frozen (4°C) Eagle's medium. These were taken to the laboratory and the Eagle's medium containing the specimen was transferred to a screw-capped tube containing a cell monolayer from which the tissue culture fluid had been removed. No more than 30 minutes elapsed between the collection of specimens and inoculation of the cultures.

Eagle's minimum essential medium without serum containing 0.15% sodium bicarbonate, 200 U/mL of penicillin, 100 µg/L of streptomycin was used for the collection of specimens and subsequently for maintenance medium. Cultures were observed daily for the presence of cytopathic effect. If the characteristic effect produced by varicella-zoster (V-Z) virus was observed, the specimen was assumed to contain V-Z virus.

The V-Z virus was isolated from vesicular fluid obtained from two of the three physician's children and from 8 of 12 vesicle fluid samples from other patients that were tested in the laboratory during this time. No virus was detected in specimens of pharyngeal or nasal secretions obtained daily from the physician's three children from approximately 4 days before to 2 days after the onset of rash. The isolate from the resident's daughter, Ellen, had been serially passed more than 200 times and was a prototype strain of V-Z virus available from the American-type tissue collection.

COMMENT

The source of the virus that infected the classmate who became ill with chickenpox 17 days following exposure to the

physician's child could not be ascertained. No skin lesions were known to be present at the time exposure occurred. Although it was assumed that infection was spread from another site or source, a diligent search was made for other contacts and none could be found. Efforts to recover virus from respiratory secretions of the physician's child on the day exposure occurred, moreover, were unsuccessful. It must be assumed that infectious virus was not in the respiratory secretions or that the test system was too insensitive to detect virus that was present. Observations that pharyngeal secretions from children with chickenpox could not be used to transmit infection to other children suggest that infectious V-Z virus might not be present in pharyngeal secretions.⁹

A systematic effort to isolate virus was successful in only 5 of 117⁸ and 2 of 22⁷ throat specimens and 3 of 22 nasal swabs obtained after the onset of rash. No virus was isolated prior to the onset of rash from 56 nasal and 57 pharyngeal specimens.⁷ It was suggested that the isolation only after onset of lesions and its infrequency might indicate that the virus isolated might have been transferred by the fingers of these children.⁷ Alternatively, the tissue culture system used for isolation may not have been sensitive enough to detect small quantities of V-Z virus present in respiratory secretions, although vesicular fluid isolates were obtained readily. In an attempt to increase the chances of isolat-

ing virus in the present study, cultures were inoculated with larger inoculum than is normally used and inoculated 30 minutes after they were collected; nasal as well as throat secretions were also examined for the presence of virus.

Since the classroom cases of chickenpox occurred at intervals of approximately 2 weeks and there were no known extracurricular sources of exposure, these cases were probably serially transmitted. These children spread their infections prior to the time their skin lesions were observed since, except for one child, their parents denied that they had attended school after the onset of rash. One child was known to have attended school while localized lesions were present on his neck. These lesions were present for 2 days prior to the time his generalized eruption was observed. Localized vesicles that had been excoriated were also observed to precede the generalized exanthem in one of the physician's preschool children.

It is possible, therefore, that localized lesions that were not noticed by the parents might have been the source of virus that infected additional children in the classroom. Virus might have been disseminated directly by the fingers of the children at the time the vesicles were broken. Our judgment that chickenpox is contagious prior to the rash is based on reports of similar epidemiological observations. In one of these reports, it was concluded that "infectivity preceding the eruptive stage in this disease

must be of short duration" as removal from a contact case 9 hours prior to onset of chickenpox resulted in diseases, whereas removal 24 hours or more prior to onset did not.¹⁰ Evans¹¹ cited two of his own experiences supporting pre-emptive contagiousness and cited some similar cases.

Although our epidemiological observations do not provide a definitive answer to whether children with chickenpox are contagious prior to the time their rash appears, they certainly indicate that a child might be contagious before the rash is observed. Even when parents made an effort to keep children with rash from school, spread of chickenpox occurred and five of the seven susceptible children in the classroom were eventually infected. Excluding children from school resulted in distributing the cases for a period of several generations. In contrast, all of the susceptible household contacts of the classroom cases developed chickenpox approximately 2 weeks following exposure. In a larger study 383 (87%) of 441 susceptible household contacts developed chickenpox about 2 weeks after the initial household case.¹²

The inevitability of chickenpox in the absence of a vaccine raises questions about the wisdom of keeping children home from school and day care who are otherwise well enough to attend.¹³ The cost of this practice in lost wages of parents who must remain at home with these children approaches \$400 million annually.¹⁴

IF DIABETES IS A DISEASE YOU CAN LIVE WITH, WHY DID 150,000 DIE LAST YEAR?

Since 1 out of every 20 people has diabetes, you probably know someone who lives with it.

But what you probably don't know is what it's like to deal with diabetes: to have to stick to a diet every single day; to constantly monitor your blood sugar level; or to take insulin injections several times daily.

And you probably didn't know that diabetes can lead to other diseases, like heart disease, kidney disease and blindness.

Or, that every year 150,000 die.

Help us find a cure for diabetes. Before you know someone who dies from it.

American Diabetes Association

Announcing

The Eleventh Annual
American Medical Association

Morris Fishbein Fellowship

July 2, 1990 through
June 28, 1991

Applications are now being taken for the Eleventh Annual Morris Fishbein Fellowship in Medical Journalism sponsored by the American Medical Association. Physicians interested in

making a substantial commitment to medical journalism are invited to apply for this full-time one-year fellowship program.

Work With JAMA The successful candidate will work with the editorial and production staff of The Journal of the American Medical Association in all facets of editing and publishing a major weekly medical journal. At the completion of the program, it is expected that the candidate will be proficient in all aspects of manuscript selection, issue makeup, copy editing and styling, art and layout of articles, issue planning and managing, in addition to the many other elements of journal publication. He/she will also be conversant with marketing and advertising procedures.

Publishing The candidate must have proved writing ability at the time of application, for he/she will be required during the course of the year to prepare such articles for publication as may be assigned. Although the fellow will work under the supervision of a physician-editor, ability to work independently is a must. Ability to use a resource library is a strong plus.

Specialty Journal Opportunity In addition to The Journal of the American Medical Association, the Fishbein Fellow will receive special insight into the different aspects of publishing a major specialty journal on a monthly timetable.

Stipend A stipend of \$30,000 will be provided to the successful candidate to cover the 1-year period.

Application Forms For an application blank, please write to: Helene M. Cole, MD, Senior Editor, Director, Department of Editorial Affairs, Journal of the American Medical Association, 535 N. Dearborn St., Chicago, IL 60610.

Deadline For Applying Completed applications should be forwarded as soon as possible and must be received no later than January 15, 1990. The successful candidate will be notified by April 2, 1990.

Educational Interventions

Hugh D. Allen, MD, Columbus, Ohio
Fredric Burg, MD, Philadelphia, Pa
Harold Levine, MPA, Galveston, Tex
Barbara Starfield, MD, Baltimore, Md
Larrie W. Greenberg, MD, Washington, DC

Purpose.—This department is intended to share information concerning educational efforts in the broad field of pediatrics. We welcome studies on the following topics: undergraduate and graduate education in medicine and allied health occupations; continuing education of health professionals; education of patients and families; and health education for the general public, the community, and organizations that contribute to the promotion and improvement of the health of children.

Editorial Comment.—*Although national guidelines for the detection of elevated lead levels in children have been developed, how well are they implemented? This study shows how evaluation criteria were developed and then used to judge how well various pediatric teaching programs implemented lead screening practices. See how they apply to your program.*—H.D.A.

Lead Screening at Pediatric Teaching Programs

Karen S. Edwards, MD, Brian W. C. Forsyth, MB, ChB, FRCP

Elevated blood lead levels continue to occur frequently in children, especially among those living in low-income inner-city neighborhoods. As evidence accumulates that the "safe" level of blood lead is lower than previously thought,¹ the ascertainment of all cases of elevated blood lead levels in children becomes even more important.

In 1985, the Centers for Disease Control (CDC), Atlanta, Ga, issued new lead poisoning prevention guidelines that state that ideally *all* children between the ages of 9 months and 6 years should be screened annually for elevated lead levels.² In 1987, the American Academy of Pediatrics (AAP) issued a similar set of guidelines.³ Both sets of guidelines describe the ideal criteria for screening, but then specify a list of priority groupings for screening if the ideal cannot be met. Neither set of guidelines

provides specific recommendations regarding arrangements for the central collection and interpretation of lead screening results or for assuring the proper follow-up of abnormal test results.

The extent to which these recommendations have been incorporated into screening practices at institutions providing health care to urban children is unknown. To our knowledge, there has not been a systematic survey of currently used methods of screening and provision of follow-up for children with elevated blood lead levels. Because the official guidelines provide only priorities for screening (Table 1) rather than a specific definition of groups that must be screened, it was expected that there would be a broad range of application of guidelines.

The purpose of this study was to determine the range of lead screening practices at urban pediatric teaching programs. Teaching programs were studied because their screening practices are likely to be propagated by their graduates and because we assumed that their screening standards would best reflect the latest guidelines. Programs in large cities were chosen to assure that the populations served would include a large proportion of high-risk children (ie, low income, minority, urban).

Programs provided information regarding age at first screening, the frequency of screening, and the extent of centralization of data collection, interpretation, and follow-up. They also provided information about possible impediments to ideal screening practices, such as the use of venipuncture to obtain screening specimens and the lack of institutional guidelines for screening. We requested information regarding the use of the following techniques that

Table 1.—Suggested Priority Groups for Lead Screening²

1. Children aged 12 to 36 months who live in, or are frequent visitors to older, dilapidated housing
2. Children aged 9 months to 6 years who are siblings, housemates, visitors, and playmates of children with known lead toxicity
3. Children aged 9 months to 6 years living in older, dilapidated housing
4. Children aged 9 months to 6 years who live near lead smelters and processing plants or whose parents or other household members participate in a lead-related occupation or hobby
5. Children aged 9 months to 6 years who live near highways with heavy traffic or near hazardous waste sites where lead is a major pollutant
6. All children 12 to 36 months of age
7. All children 9 months to 6 years of age

might improve the completeness of screening: on-site free erythrocyte protoporphyrin (FEP) determination, the use of fingerstick capillary specimens, and a review by institutions of their own screening programs.

METHODS

The largest residency training programs (judged by the number of positions available) in northeastern US cities with populations greater than 100 000 were chosen to participate in our survey.⁴ Telephone contact was made in the spring of 1987 by one of us (K.S.E.) with the office of each pediatric department's chairperson to determine the name of the individual in charge of lead screening in the outpatient department. A program was not included in the study if contact with that individual was not established after three attempts. After we explained the survey by telephone and the contact person agreed to participate, the survey was mailed. Participants were guaranteed personal and program anonymity. A second mailing was sent to nonresponders.

The survey consisted of 15 multiple-choice or short-answer questions concerning protocols for lead screening and characteristics of the population served. Table 2 shows the questions in an abbreviated form. Respondents were asked to estimate numbers or percentages when an actual number or percentage was not available, and they were asked to note when a response was only an estimate.

Table 2.—Abbreviated Summary of Questionnaire Items

1. Characterize the program as urban, suburban, or rural
2. What proportions of Hispanic, black, white, or other groups are served by the program?
3. What are the proportions of payment method for visits (self-pay, private insurance, medical assistance)?
4. What is the initial lead screening test used?
5. Is the initial screening step standardized?
6. What is the upper limit of normal levels for free erythrocyte protoporphyrin, zpp, and lead?
7. At what age are children first screened?
8. How frequently are children screened?
9. What percentage of children seen for well-child care are being screened?
10. Are results of capillary free erythrocyte protoporphyrin determinations available prior to the child's departure from the clinic?
11. Who is responsible for the follow-up of children with abnormal screening test results?

ANALYSIS

We developed criteria to evaluate the screening programs based in part on current official screening guidelines. Criteria taken directly from the guidelines were a first screening by 12 months of age and screening at least yearly thereafter. Although the official guidelines do not call for centralization of screening results and follow-up, the need for such a system is obvious and we included it as the third criterion. Screening programs meeting all three criteria were judged to be adequate.

RESULTS

Twenty-two (78%) of the 28 surveys were returned completed. All 22 programs characterized themselves as urban (rather than suburban or rural). All programs except 1 served populations that were at least 40% minority. At 9 of the programs, 80% or more of the population served were from minority groups. The proportion of the population receiving medical assistance at each center ranged from 40% to 80%.

Programs were scored for the presence or absence of the three criteria

(first screening by 12 months of age, annual screening, and centralization of screening results and follow-up). The results are shown in Table 3. Six programs (27%) met all three criteria and were judged adequate. Four programs (18%) met none of the criteria. The remaining 12 programs (55%) met only one or two of the criteria.

The most frequently met criterion was annual screening, which was done at 16 (72%) of the programs. At 10 of the 22 programs, children were first screened *later* than the recommended age of 12 months, with some programs screening for the first time as late as 18 to 30 months of age. Half of the programs lacked a mechanism within the institution for centralization of collection and interpretation of screening results and for arranging a follow-up of abnormal test results.

Three of the four programs that met none of the criteria were the only three programs to indicate that there was no institutional protocol for lead screening, and that each practitioner followed his or her own protocol for screening, inter-

pretation, and follow-up of results. All other institutions reported that a specific protocol was provided for the use of all practitioners.

Half of the programs stated that 90% or more of the population served were being screened. Five of the programs did not provide information on the extent of screening. Of the 6 programs reporting less than 90% screening, 2 served populations in which fewer than 50% used medical assistance and fewer than 50% were from minority groups. Of the 17 programs that provided a percentage of the population screened, all but 3 provided estimates. The 3 programs providing actual percentages obtained them by routine institutional review of patient care, either by review of medical records or by review of computer-stored patient data.

Venipuncture was reported as the primary method of obtaining screening specimens by seven (32%) of the programs. Seven programs reported never using fingerstick capillary methods to obtain initial screening specimens. Fifteen programs used a fingerstick as either the primary or alternate method of obtaining screening specimens. Only five (23%) of the programs could obtain an FEP result prior to a child's departure from the clinic.

When asked to indicate the upper limit of acceptable FEP for screening purposes, two directors provided incorrectly high values (60 and 50 $\mu\text{g/dL}$) instead of the recommended value of 35 $\mu\text{g/dL}$. Only three of the programs routinely reviewed their own lead screening practices. Two programs did this by periodically reviewing a number of charts. One program used information from a computerized database of patient records.

COMMENT

Official lead screening guidelines leave much latitude for determining which children to screen. It seems appropriate, in light of the increasing evidence of the deleterious effect of even low-level lead exposure, that the strict-

est interpretation should apply to the screening of high-risk, low-income, inner-city children being served by the programs surveyed.

When we applied our strict set of criteria to screening practices at urban pediatric teaching programs, only 27% met all three criteria. Forty-five percent of the programs reported the initiation of lead screening after the age of 12 months. This practice leaves children unscreened at the age of highest risk for the deleterious effects of undue lead exposure. The lack of central coordination of screening data and follow-up at 50% of the programs weakens the important link between testing and abatement and treatment.

While we were unable to investigate an association between program characteristics and screening adequacy using our data, we were able to determine the frequency of certain practices that are likely to decrease the adequacy of screening.

The lack of institutional guidelines for lead screening was reported by three of the four programs that met none of the criteria for adequate screening. All other institutions stated that a protocol was provided to its practitioners.

The use of venipuncture specimens for screening probably limits the number of children screened because of the extra time required for venipuncture, a reluctance to subject children to venipuncture, and, in some instances, the requirement that the specimen be obtained by the pediatric practitioner. In our experience, the changeover from screening using venous specimens obtained by physicians to using FEP determinations on capillary samples obtained by a trained technician was accompanied by a dramatic increase in the number of children screened. (K.S.E. and B.W.C.F., unpublished data, 1987). Hematofluorometers may be purchased for approximately \$5000, are easily operated, and specimens to be used as controls may be purchased from the distributor.

The ability to obtain the results of a capillary sample FEP prior to discharging the child from the clinic lends several obvious advantages to a screen program. It obviates the need for venous samples in children with a normal FEP value. It allows venous samples to be drawn immediately on all children with elevated FEP values, therefore eliminating the need for often difficult to arrange return visit phlebotomy.

The limitations of this study include the fact that the characteristics of a screening program were obtained by questioning the head of the program rather than by an actual review of program practices. Because most programs had not reviewed their own screening practices, the directors' responses might not reflect actual practices.

It is likely that lead screening guidelines will be reviewed in the near future to attempt to increase the likelihood of detecting and intervening in even low lead exposure cases. Our study indicates that the current guidelines are frequently not being met even at teaching institutions. It is time for each institution providing well-child care to review its lead screening practices and to prepare for a more intensified effort to detect undue lead exposure.

We thank the program directors who participated in this study and shared their suggestions for improvement of screening programs and M. Harris for preparing the manuscript.

Regulation of Oxygen Concentration Delivered to Infants Via Nasal Cannulas

Nestor E. Vain, MD; Luis M. Prudent, MD; Deborah P. Stevens, RRT;
Margaret M. Weeter, RRT; M. Jeffrey Maisels, MB, BCh

• The administration of oxygen to infants via nasal cannulas is now a common practice in neonatal units although the inspired oxygen concentration reaching the patient's airway is unknown. We measured the hypopharyngeal oxygen concentration in 10 infants who were receiving oxygen via nasal cannulas and assessed the impact of changes in the flow rate and inspired oxygen concentration. Weaning these infants by reducing the flow rate, even if changes are slight, produces clinically important changes in the oxygen concentration reaching the airway. Such changes are poorly tolerated by infants with chronic lung disease. Changing the flow rate and inspired oxygen concentration, rather than the flow rate alone, provides greater precision and is likely to avoid excessive and abrupt changes in the oxygen concentration reaching the airway.

(AJDC. 1989;143:1458-1460)

Oxygen is commonly delivered via nasal cannulas to infants with prolonged oxygen requirements. This practice has simplified nursing care considerably and facilitated early discharge of these infants, permitting the administration of supplemental oxygen at home.¹⁻⁴ This technique makes it difficult, however, to determine the actual fraction of inspired oxygen concentration (F_{IO_2}). Knowledge of the required F_{IO_2} may be important to assess the

clinical course and the response to therapy (eg, diuretics), particularly when planning discharge from the hospital.

To control the F_{IO_2} , most clinicians vary the flow rate through the nasal cannula, while the oxygen source is kept constant.⁵ As the infant breathes, however, air enters from the mouth and around the nasal cannula, and the actual oxygen concentration reaching the airway is unknown.

Since the hypopharyngeal oxygen concentration (F_{Ho_2}) is virtually identical to the tracheal oxygen concentration,^{6,7} we decided to perform direct determinations of the oxygen concentration reaching the patient's airway by measuring the F_{Ho_2} at various flow rates. Our purpose was to provide guidance for physicians who administer oxygen through nasal cannulas and to assess oxygen delivery during weaning.

PATIENTS AND METHODS

We studied 10 infants in clinically stable condition who were receiving oxygen via nasal cannulas. The clinical characteristics of the infants are listed in the Table. The median birth weight was 1290 g (range, 825 to 4090 g), and the median weight at the time of the study was 2130 g (range, 1780 to 4090 g). The median gestational age at birth was 29 weeks (range, 25 to 39 weeks), and the median postnatal age at the time of the study was 52.5 days (range, 19 to 123 days). With one exception, all patients had received mechanical ventilation (median duration of assisted ventilation, 32 days; range, 0 to 75 days).

We monitored the heart rate, respiratory rate, transcutaneous oxygen tension ($TcPo_2$) (Novamatrix, Wallingford, Conn), and oxygen saturation (by pulse oximetry, Biox 3700 Pulse Oxymeter, Ohmeda, Boulder, Colo) throughout the study. Oxygen was delivered to the infants via nasal cannulas (infant Nasal Cannulas 1601, Salter Laboratories, Arvin, Calif), and we sampled the F_{Ho_2} by using a modification of the nasal

oxygen sampler (Fig 1).⁸ We measured oxygen concentrations with a polarographic oxygen analyzer. The $TcPo_2$ electrode was calibrated with a zero solution and room air according to the manufacturer's directions.

A 12F suction catheter was introduced through the infant's mouth into the hypopharynx. The depth of insertion was equal to the distance from the mouth to the earlobe. The catheter was secured with tape, and samples were drawn with the infants at rest when the vital signs, $TcPo_2$, and oxygen saturation were stable. Measurements of the F_{Ho_2} were obtained by drawing the gas samples slowly into the syringe during a period of 60 to 90 seconds. Samples were obtained throughout various respiratory cycles (inspiration and expiration), and sampling continued until the oxygen analyzer readings remained stable. The desired F_{IO_2} was obtained by using a flow oxygen blender (Bird HI/LO). The F_{IO_2} was measured before each hypopharyngeal sampling via a three-way stopcock that was placed in line between the flowmeter and the nasal cannula. The flow rate was selected at the blender's low-flow outlet by using a pressure-compensated flowmeter (Timeter 0-3 Flowmeter, Timeter Instrument Corp, Lancaster, Pa). The accuracy of the flowmeter was evaluated by measuring the actual flow with a calibration analyzer (Timeter RT 200).

By using a Latin square design, infants were assigned randomly to various gas flow rates (0.25, 0.50, 0.75, and 1.0 L/min) and oxygen concentrations (100%, 80%, 60%, and 40%). Readings were obtained when the $TcPo_2$ and oxygen saturation readings were stable (3 to 5 minutes after a change in settings). Each patient was studied with each combination of flow rate and F_{IO_2} as long as the $TcPo_2$ and oxygen saturations were maintained within acceptable limits ($TcPo_2$, 40 to 80 mm Hg; oxygen saturation, 85% to 97%). The flow rate and/or F_{IO_2} were adjusted when these limits were exceeded. Thus, not every patient was exposed to each F_{IO_2} /flow rate combination (Fig 2). The protocol was approved by our Clinical Investigation Committee, and parental consent was ob-

tained for each study. Analysis of variance was used to determine the effect of changes in the flow rate and blender setting on the $F_{H_{O_2}}$.

RESULTS

The results are shown in Fig 2. For each blender setting and flow rate, the differences in the $F_{H_{O_2}}$ were significant ($P < .001$). We measured the $F_{H_{O_2}}$ in five infants who were breathing room air at flow rates of 0.25 to 1.0 L/min. In all cases, the $F_{H_{O_2}}$ ranged from 0.16 to 0.18. We also determined the $F_{H_{O_2}}$ (without modifying the flowmeter or blender settings) in five patients who cried during part of the study period. The $F_{H_{O_2}}$ decreased during crying by $17.7\% \pm 5.4\%$ (mean \pm SD) from baseline values, and subsequently, it increased when the infant stopped crying. These changes were followed by similar changes in the $TcPO_2$ and oxygen saturation.

COMMENT

Since the tracheal oxygen concentration is almost identical to the $F_{H_{O_2}}$,^{6,7} and arterial oxygenation correlates more closely with the $F_{H_{O_2}}$ than with the settings of the gas delivery systems,⁷ we thought it important to document the actual oxygen requirements (by measuring the $F_{H_{O_2}}$) to monitor the severity of the pulmonary disease.

By using a similar method in adults, Schacter et al⁷ reported that the $F_{H_{O_2}}$ decreases at higher respiratory rates and with mouth breathing. We did not analyze respiratory patterns, but we observed an average decrease in the $F_{H_{O_2}}$ of 17.7% when infants cried and a subsequent increase when they stopped crying. These changes in the $F_{H_{O_2}}$ were followed by similar changes in the $TcPO_2$ and oxygen saturation. When infants breathed room air at various flow rates, the $F_{H_{O_2}}$ was 0.16 to 0.18 in all cases, indicating mixing between inspired and expired gases.

Fan and Voyles⁶ used an indirect method to calculate the oxygen requirements of these patients. They administered 100% oxygen via a nasal cannula and adjusted the flow rate to obtain a $TcPO_2$ similar to that obtained when a known F_{IO_2} was administered via an oxygen hood. By using their recommendations to calculate the oxygen flow when

Fig 1.—Hypopharyngeal oxygen (O_2) sampler. A rubber ring was used to fit the analyzer probe securely to the Bird T piece that was connected to a 12F suction catheter and a 60-mL syringe via 15-mm adapters and endotracheal tube adapters. The system was made airtight by sealing the plastic adapters with ethylene dichloride cement.

Fig 2.—Hypopharyngeal oxygen concentration ($F_{H_{O_2}}$) by flow rate and inspired oxygen concentration. Seven to nine measurements were obtained at each setting, with the exception of 0. and 0.25 L/min at an inspired oxygen concentration of 40% where six and five measurements respectively, were obtained.

switching an infant from an oxygen hood to a nasal cannula, we frequently found TePO_2 values to be higher than predicted. The patients who were studied by Fan and Voyles,⁶ however, were significantly larger than ours (mean weight, 3155 vs 2130 g, respectively), and five of their infants weighed more than 3500 g. Because smaller infants have a small inspiratory flow and minute ventilation, they entrain less room air, and the oxygen concentration reaching the airway is likely to be greater. By using regression analysis, however, we did not find a significant inverse relationship between the Fho_2 and weight when the flow remained constant.

Infants in stable condition with chronic lung disease are frequently switched from an oxygen hood to nasal cannulas. Subsequently, weaning is performed by lowering the flow rate, usually in 0.125- to 0.25-L/min decrements. Figure 2 shows that a decrease in the flow rate from 0.75 to 0.50 L/min, at an FIO_2 of 1.0, represents a drop in the Fho_2 from 0.60 to 0.44. Similarly, discontinuing oxygen therapy from a previous flow rate of 0.25 L/min, at an FIO_2 of 1.0, decreases the Fho_2 from 0.34 to 0.17 or to 0.18. It is not unusual to observe a large drop in a patient's TePO_2 or oxygen saturation when oxygen is discontinued in this manner. Changes of this magnitude are poorly tolerated by

infants with bronchopulmonary dysplasia and are seldom attempted in infants who receive oxygen via hoods.

Flowmeters that are capable of delivering lower rates (0.125 L/min) might be more useful for these patients but were not available in our unit at the time of this study. However, Fig 2 shows that decreasing the flow from 1.0 to 0.25 L/min at an FIO_2 of 1 results in a drop of approximately 30% in Fho_2 . Assuming a linear relationship, a decrease of 0.125 L/min would lower the Fho_2 by approximately 5%, an unacceptably large change in clinical practice.

Although our data suggest that greater precision can be achieved by modifying both the FIO_2 and flow rate during the process of weaning, inspection of Fig 2 indicates that reducing the FIO_2 below 60% has little utility because of the minimal change in the Fho_2 that occurs with a change in the flow. As a practical guideline, it appears that weaning should be initiated at an FIO_2 of 100% by decreasing the flow rate from 1.0 to 0.25 L/min. For the next step, the flow rate should be returned to 0.75 L/min at an FIO_2 of 80%, followed by a decrease in the flow rate to 0.25 L/min. The same sequence can be applied at an FIO_2 of 60%. There does not appear to be any advantage in decreasing FIO_2 concentrations below 60%, and once this level has been reached, a decrease in the

flow rate alone is the preferred course of action.

Although our method for measuring the Fho_2 is simple, it is not practical for everyday clinical use. The data in Fig 2 can be used, however, to provide an estimate of the appropriate flow rate and FIO_2 . The SDs show that a considerable individual variation in the Fho_2 may, nevertheless, occur, and independent verification of blood oxygenation is necessary at appropriate intervals. The application of this technique should, therefore, be limited to well-controlled inpatient settings.

We are most grateful to Dean Hess, MEd, RRT, for his generous assistance, and to Waldemar Carlo, MD, for his critical review.

Congenital Cardiovascular Malformations in Twins and Triplets From a Population-Based Study

Kate A. Berg, PhD; Jacqueline A. Astemborski, MHS; Joann A. Boughman, PhD; Charlotte Ferencz, MD, MPH

• Data from the Baltimore-Washington Infant Study of congenital cardiovascular malformations permitted detailed analysis of congenital cardiovascular malformations in 62 twins and 3 triplets and 2303 singleton cases. A probability sample of controls ($n = 2793$) included 43 twins. The case prevalence of multiple births was 28 of 1000, compared with a 15 of 1000 prevalence among controls ($\chi^2 = 5.7$). There were more girls among case twins than among case singletons and controls ($\chi^2 = 9.0$). Monozygosity was no more frequent in case twins than in controls. Looping defects occurred in 4 monozygotic twin pairs compared with only 1 dizygotic twin pair. The twinning process itself may be implicated in the development of congenital cardiovascular malformations in some of these infants, especially those with looping defects, but concordance of types of defects in 4 of 65 pairs implicates genetic factors in the determination of some forms of congenital cardiovascular malformations.

(AJDC. 1989;143:1461-1463)

Human twins are a unique resource for evaluating genetic and environmental contributions to the etiology of birth defects such as congenital cardiovascular malformations (CCVM). Although familial aggregation has been demonstrated consistently for CCVM,¹ studies of twins with this common group of birth defects have failed to confirm a significant genetic component.²⁻⁴ Clinical and epidemiological studies of CCVM have reported an increased frequency of these malformations among same-sex twins.^{3,5-7} The cause of this apparent excess has been attributed to the potentially teratogenic effect of the monozygotic twinning process itself.⁸

An accurate estimation of the preva-

lence and determination of types of CCVM among twins compared with those among singletons has not yet been achieved. Data available on multiple births from the Baltimore-Washington Infant Study (BWIS), a population-based case-control study of CCVM, permit a detailed descriptive analysis of heart defects in multiple births compared with heart defects in singletons. We were thus able to address the following issues: (1) prevalence of CCVM in twins compared with prevalence in singletons; (2) the frequency of monozygosity and dizygosity among affected twins; (3) the sex ratio of case twins, compared with sex ratio of case singletons; (4) concordance for CCVM among pairs of monozygotic twins and dizygotic twins; and (5) evidence of genetic factors contributing to CCVM.

METHODS

Data for this study came from all infants enrolled in the BWIS between January 1981 and December 1986. The BWIS is an ongoing case-control study of the resident birth cohort of the State of Maryland, the District of Columbia, and six counties in Northern Virginia, an area of approximately 90 000 annual births.⁹ Virtually complete ascertainment of all liveborn infants in the first year of life with confirmed CCVM is achieved through multiple case sources including 6 pediatric cardiology centers and 52 collaborating hospitals. A systematic review of autopsy logbooks at community hospitals, together with an annual review of death certificates, ascertains unreferred cases.¹⁰

Cases are defined as infants less than 1 year old with structural cardiac abnormalities confirmed by echocardiography, cardiac catheterization, surgery, or autopsy. Patent ductus arteriosus in premature infants (gestational age, <38 weeks) is excluded. Control infants had, by definition, no cardiac defects. A probability sample of control infants was selected by computer algorithm to be representative of the birth cohort within area hospitals.¹⁰ Strict confidentiality is maintained for all data gathered from human subjects, and the BWIS has institutional Human Subjects Review Board approval.

When multiple members of a twin or trip-

let set have CCVM, only the firstborn infant is considered a "case." Zygosity is determined chiefly by the mothers' reports, since information regarding placentation or serological markers is usually unavailable.

Congenital cardiovascular malformations were classified into embryonic mechanistic groups using the system of Clark¹¹: (1) truncal malformations, such as tetralogy of Fallot; (2) hemodynamic abnormalities, such as perimembranous ventricular septal defect; (3) extracellular matrix abnormalities such as atrioventricular canal; (4) excessive cellular death, such as Ebstein's anomaly; and a group of as yet unverified categories (5a) looping abnormalities, such as levocardia; (5b) targeted growth abnormalities such as total anomalous pulmonary venous return; (5c) and other defects, such as pulmonary vein stenosis. The advantage of this classification system is that it permits aggregation of seemingly diverse anatomic defects into groups that are hypothesized to be developmentally related.

RESULTS

From 1981 to 1986, 62 case twins (of whom 2 pairs were conjoined) and 3 case triplets were included among the 2303 case infants whose parents were interviewed in the BWIS. In this analysis conjoined twin pairs were classified as case twin and 1 cotwin. Among 2793 control infants, there were 43 infants from multiple gestations, none of whom was conjoined or a triplet.

Cases were almost twice as likely as controls to be from a multiple birth (2.8% of cases and 1.5% of controls; $P < .03$, Table 1). However, the distribution of zygosity was very similar among case infants (33.9% were monozygotic) and control infants (27.9% were monozygotic), with no significant excess of monozygosity observed in case ($\chi^2 = 0.413$). There were significantly more girls than boys in the case group compared with twins in the control group ($\chi^2 = 9.0$, $P < .005$, Table 1), while the ratio of male to female infants among case singletons was equal to that among controls.

Some types of CCVM, such as aort

*MZ denotes monozygotic; DZ, dizygotic; and UZ, unknown zygosity.

versely, secundum atrial septal defect, with a reported excess in girls, was diagnosed in five twin boys but no twin girls.

The types of CCVM noted in twins and singletons are compared in Table 3. Conotruncal and targeted growth defects were slightly less common in twins than in singletons, although the small number of twins with these defects made rigorous statistical comparison problematic. With the exception of the slight, but not significant, increase in the looping defect category among twins compared with singletons, the other groups were similar in proportions. Looping defects occurred in 4 (18.2%) of 22 monozygotic twins, but only 1 (2.5%) of 40 dizygotic twins.

Among the nonconjoined twins, 4 case twins had a cotwin with CCVM. Of the 20 pairs of monozygotic nonconjoined twins, there were 2 pairs (10%) of twins in which both members of the pair were affected. In 1 pair, both had secundum atrial septal defect, while in the other, 1 twin had pulmonary valve stenosis and 1 had perimembranous ventricular septal defect. Of the 40 dizygotic twin and triplet sets, 2 (2.5%) had affected cotwins. One set of triplets had 2 affected members, 1 with bicuspid aortic valve and the other with hypoplastic left heart syndrome. In addition, both members of a pair of twins of unknown zygosity had atrioventricular canal. Each of the affected twin sets were concordant for mechanistic group, but not necessarily for specific anatomical defect.

Extracardiac anomalies occurred in 15 case twins (23.1%) and in none of the control twins in the BWIS. Cytogenetic anomalies were not reported in any of

the monozygotic case twins and in only 3 of the dizygotic case twins (trisomies 13, 18, and 21). Among case twins with non-cytogenetic extracardiac anomalies, 2 monozygotic twins had umbilical hernias, and 1 had a diaphragmatic hernia. The 2 pairs of conjoined twins had multiple malformations. Two dizygotic case twins had omphaloceles, 1 had pectus excavatum, 1 had aniridia, 1 had microcephaly, and 1 had VATER association. One case twin of unknown zygosity had a limb reduction defect, a cleft palate, and an absent humerus.

COMMENT

The BWIS attempts to achieve complete ascertainment of all confirmed CCVM in the resident birth cohort including CCVM in multiple gestations. Diagnostic criteria are deliberately strict to prevent inclusion of potentially innocent murmurs detected only by auscultation and otherwise unconfirmed. Although previous studies have suggested a higher prevalence of CCVM, there is agreement that the prevalence of confirmed CCVM is approximately 4 per 1000 among liveborn infants under 1 year of age.¹³

In the BWIS, there was an excess of case twins compared with control twins. An association between multiple births and CCVM has been observed by others in epidemiological studies of birth defects using both prospective and retrospective methods.^{3,7} Twinning itself may contribute to the development of cardiac defects if the presence of two embryos developing in the same uterus alters the "biological clock" of one or both.¹⁴

In the BWIS, the distribution of zygosity was similar in multiple gestations

in cases and controls. In contrast to previous studies in which an excess of monozygotic twins has been reported,^{3,6} results from some of these earlier series may have reflected ascertainment bias for monozygotic twins, or lack of systematic diagnosis of heart defects. In our study, zygosity information was available only through mothers' reports rather than by examination of the placentas or serological markers. The latter two methods are preferable, but when these methods have not been used, the questionnaire method of zygosity determination has been employed with nearly comparable results.¹⁵

More female case twins were reported in the BWIS, a finding also noted by Anderson.² The reason for an excess of twin girls among liveborn cases of cardiac malformation is difficult to determine, since female singletons with CCVM are not overrepresented. In an unselected series of spontaneously aborted twins with and without heart defects, female twin pairs were more likely to be aborted earlier in gestation, while male twin pairs were more frequently aborted toward the end of the pregnancy.¹⁶ This suggests differential survival of female twins who, if not aborted early, may be more likely to be born alive even with a heart defect. Measurement of differential survival was not possible using data from the BWIS, which ascertains only liveborn infants. Carefully designed fetal echocardiography studies may help to resolve questions about both the apparently altered sex ratio in twins with CCVM and the incidence of CCVM in

twins compared with singletons.

Looping abnormalities accounted for almost twice the proportion of twins compared with the proportion of singletons (7.7% and 3.9%, respectively), and were also more frequently reported in monozygotic than in dizygotic twins. Looping abnormalities may represent disturbances of laterality. Burn and Corney⁶ attributed the excess of same-sex twins to defects related to cleavage of the single zygote, and they suggested that a disturbance of laterality should be more common in monozygotic twins.

The lack of concordance in monozygotic twins has been used as evidence that there is little or no genetic contribution to the etiology of heart defects.⁷ The results of this twin analysis of population-based case-control data did not directly support that conclusion, as 10% of the monozygotic but only 2.5% of the dizygotic cases had affected cotwins. The use of a classification system of heart defects that permits grouping of lesions by presumed pathogenic mechanism has proved useful in studying the familial recurrence of CCVM in human families¹ and may be equally useful in evaluating concordance in twins since it highlights similarities that may be overlooked when an anatomic classification system is used.

The proportion and type of extracardiac anomalies were different in case twins compared with case singletons and with controls. Bearing in mind that the numbers are small, there were relatively few cytogenetic anomalies in case twins compared with case singletons.¹⁷ This may be due to selection, since aneuploidy is associated with a very high

spontaneous abortion rate.¹⁸ Aneuploidy and a heart defect may be relatively incompatible with survival to live birth. Noncytogenetic extracardiac anomalies were relatively common in case twins. This may reflect a teratogenic effect of twinning itself, since none of the case twins with extracardiac anomalies had similarly affected cotwins.

In summary, we found that (1) heart defects occurred in excess among multiple gestations, but the distribution of zygosity was not different among cases with CCVM compared with controls; (2) looping abnormalities appeared to be increased; and (3) among twin pairs, only 6.2% had a cotwin with CCVM, but the defects were concordant by mechanistic group.

These findings lead us to speculate that the twinning process may be related or contributory to the development of CCVM, particularly looping and conotruncal defects. This process would not be expected to affect both members of a twin pair equally. This may account for the large proportion of discordant twin pairs. However, since all sets in which multiple members were affected showed concordance for mechanistic group, the suggestion remains that development of cardiac defects at some level may be under genetic control.

This study was supported in part by grant HL25629 from the National Heart, Lung, and Blood Institute and National Research Service Award grant NR0533203 and the Alpha Phi Foundation, Baltimore, Md.

We thank Catherine A. Neill, MD, Emily L. Harris, PhD, and Joel I. Brenner, MD, for their helpful comments. We also thank Linda Finazzo and Kimberly Hofmeister for their technical assistance, and acknowledge the help of all members of the BWIS investigative team.

Nonphenylketonuric Hyperphenylalaninemia

Mary Joann Lang, PhD; Richard Koch, MD; Karol Fishler, PhD; Robert Baker PhD

• Sixteen subjects with nonphenylketonuric hyperphenylalaninemia were followed up during a period of years. Dietary treatment did not seem to influence the outcome, and no relationship between blood phenylalanine and intellectual outcome was demonstrable.

(AJDC. 1989;143:1464-1466)

It was some years after phenylketonuria (PKU) was described by Fölling,¹ that clinicians became aware of milder forms of hyperphenylalaninemia. Terminology for the various degrees of hyperphenylalaninemia was confusing.² In addition, it was unclear what levels of phenylalanine required dietary treatment.³

In an attempt to elucidate the long-term outcome of children with milder forms of hyperphenylalaninemia, it was decided to follow up all patients more than 5 years old with non-PKU hyperphenylalaninemia, seen at the Childrens Hospital of Los Angeles since 1957. It was possible to locate 20 such children, some of whom were treated for a time with a phenylalanine-restricted diet while others were not. Often treatment with the phenylalanine-restricted diet was instituted because the index case was thought initially to have classic PKU or because the clinician in charge based his or her decision to treat on some arbitrary value such as "over 720" $\mu\text{mol/L}$ or "over 900" $\mu\text{mol/L}$. The major reason for confusion regarding treatment was that good data documenting dietary benefit or lack thereof were not available. The largest published series consisted of 14 chil-

dren⁴ with mild hyperphenylalaninemia seen at the Boston (Mass) Children's Hospital. Thus it was hoped that this review of experience at the Childrens Hospital of Los Angeles would shed additional information on the natural history of children with non-PKU hyperphenylalaninemia.

METHODS

Since 1957, infants and children with all degrees of hyperphenylalaninemia have been referred for evaluation to the PKU Clinic at Childrens Hospital of Los Angeles. Twenty children met the following criteria and were included in our study:

1. phenylalanine blood levels, on a normal diet, between 240 and 1199 $\mu\text{mol/L}$ and normal bipterin studies in urine.
2. a typical response on a natural protein challenge of 180 mg/kg per day of phenylalanine for 3 days with blood phenylalanine levels less than 1200 $\mu\text{mol/L}$ and absent-to-little excretion of organic acids in the urine.
3. identification by either newborn screening programs or sibling testing in affected families.
4. age older than 5 years.

The Wechsler Intelligence Scale for Children-Revised was administered to provide a global index of current intellectual function.⁵ For persons older than 16 years, the Wechsler Adult Intelligence Scale-Revised⁶ was administered. The Bender Visual-Motor Gestalt Test⁷ for children was given to assess perceptual motor function utilizing the Kopitz⁸ scoring system for determining mental age. The Wide Range Achievement Test⁹ was used to measure academic achievement in reading, spelling, and arithmetic, and the Vineland Social Maturity Scale¹⁰ was administered as a measure of social competence. The PKU Collaborative Study Family Evaluation Form measured family stability¹¹ and provided an overall view of family function. Since this is an unstandardized procedure, the Two-Factor Index of Social Position¹² (Hollingshead Scale) provided additional information necessary to evaluate family stability. Due to the small sample size, nonparametric test procedures as well as cluster analysis were employed. Spearman Rank Order Correlations and the Mann-Whitney U test were also utilized.

DESCRIPTION OF THE SAMPLE

Four of the 20 families decided not to participate due to travel limitations or time restrictions. Of the remaining 16 patients, 9 were female and 7 male. All were white and averaged 15 years of age, ranging from 5 to 39 years. Nine patients had been on a restricted phenylalanine diet for varying periods. The 2 oldest patients (ages 30 and 39 years) were born prior to availability of treatment. The 5 youngest were untreated because our experience suggested that dietary treatment was unnecessary.

The pregnancy history of the mother of each child was ascertained and found to be normal as was birth weight and early development. Three families had two patients each; thus, there were 13 family cohorts. Two families had a history of hypertension, but there were no major congenital anomalies or other metabolic disease. There was a history of depression in one patient who was treated with the phenylalanine-restricted diet and in one who was not. Another patient received counseling for emotional difficulties in school and yet another required academic tutoring while attending regular school. Except for these four patients, all others appeared to be remarkably free of extraneous factors that might have altered normal development. One patient had been slightly premature, weighing 2200 g and measuring 43 cm in length at birth.

RESULTS

We identified two clusters: one treated and the other untreated. The first group consisted of 9 patients who had received a phenylalanine-restricted diet for an average of 4 years 3 months (range, 1 to 9 years). None of these were on dietary restriction at the time of assessment for this study. Among the treated patients the mean IQ was 98.5, compared with an associated maternal mean IQ of 114. Among the 7 untreated patients the mean IQ was 101.6, with an

associated maternal mean IQ of 106.7. The mean IQ of all 16 patients was 99.9, compared with a maternal mean IQ of 110.8. Due to the small sample size and due to the fact that adults were tested with the Wechsler Adult Intelligence Scale and the children with the Wechsler Intelligence Scale for Children, this difference was not considered significant.

Table 1 delineates blood phenylalanine levels; overall, verbal, and performance IQ scores; Wide Range Achievement scores in reading, spelling, and arithmetic; Bender Koppitz scores; and Vineland Social Maturity results at the time of the study. These data were analyzed by the Spearman Rank Order Correlation. All of the correlations of IQ with current phenylalanine levels were negative, ranging from -0.107 to -0.176 . There was no consistent correlation between blood phenylalanine level and IQ results. Four patients exhibited phenylalanine levels above $900 \mu\text{mol/L}$ at the time of testing; none displayed the usual findings of classic PKU.

Additional analyses were made to investigate the possible beneficial effects of diet therapy on educational achievement or behavior. These data again did not reveal any significant beneficial association between diet therapy and the

assessments utilized in this study, namely the Wechsler Intelligence Scale for Children, Wechsler Adult Intelligence Scale, Wide Range Achievement Test, Bender Gestalt, or the Vineland Social Maturity Scale.

Since the degree of dietary adherence (compliance) and duration of dietary therapy could also be factors¹⁸ that might influence outcome, these two items were also evaluated. Compliance was evaluated by serial phenylalanine levels. Again no significant correlations were found between adherence to diet and/or outcome, or duration of therapy and outcome as measured by IQ, academic achievement, or behavior.

Correlations were also sought between the Hollingshead Two-Factor Indices of Social Position and the results of intelligence and behavior tests (Table 2). In this case the Hollingshead Score was used as an indicator of factors or influences that might enhance the likelihood of dietary compliance. A significant negative correlation was demonstrable between this measure and verbal IQ scores ($P < .02$) and performance IQ scores ($P < .01$). A similar analysis in this group of treated subjects of Hollingshead Indices with Wide Range Achievement Test scores revealed a significant negative correlation with reading ($P < .01$) but not with spell-

ing ($P > .05$) and arithmetic ($P > .05$). A positive correlation was observed between the Bender Gestalt Visual Motor Test and the Hollingshead Scores ($P < .05$). However, a negative correlation was observed between the Vineland Social Maturity Scale and the Hollingshead Scores ($P > .05$). Finally there was no significant correlation between the PKU Collaborative Study Family Evaluation Form and outcome of the treated and untreated patients. These results demonstrate the lack of a consistent relationship between compliance with and duration of dietary therapy and psychoeducational outcome in these patients (Table 2).

COMMENT

The following classification is accepted in most centers treating children for PKU, and is the basis of this report.

Classic PKU refers to individuals with the following: elevated phenylalanine levels generally exceeding $1200 \mu\text{mol/L}$ on a regular diet; excretion of the typical organic acid metabolites of phenylalanine in the urine; and little to no phenylalanine hydroxylase activity in the liver. Without treatment these individuals usually are severely mentally retarded and develop neurological signs and symptoms over a period of months or years.³

Atypical PKU is descriptive of indi-

viduals with blood phenylalanine levels of 600 to 1199 $\mu\text{mol/L}$ who usually remain asymptomatic without specific dietary treatment and may not excrete significant amounts of phenylalanine metabolites in their urine. Phenylalanine hydroxylase is significantly decreased in the liver and ranges from a few degrees of activity to as high as 5% to 10% of the normal activity.

Benign persistent hyperphenylalaninemia refers to persons with blood phenylalanine levels of 240 to 599 $\mu\text{mol/L}$ and normal urinary findings that do not require treatment.

The purpose of this investigation was to evaluate the impact of non-PKU hyperphenylalaninemia on the mental and physical health of affected individuals. We also assessed whether a phenylalanine-restricted diet during the early years of life was effective in promoting better psychoeducational achievement. While dietary restriction of phenylalanine is the accepted mode of treatment for classic PKU,¹⁸ the treatment of milder forms of hyperphenylalaninemia has varied considerably in different PKU treatment centers.¹⁴ Our data do not substantiate any beneficial effect of dietary phenylalanine restriction in individuals with non-PKU hyperphenylalaninemia during early childhood, and is in agreement with a much earlier report by Levy et al⁴ in 1971. Furthermore, the data do not indicate any relationship of the level of IQ and psychoeducational achievement with blood levels of phenylalanine. This latter finding may be consistent with the finding by Holtzman et al¹⁵ that there may be a threshold of blood phenylalanine below which intel-

lectual damage does not occur in classic PKU.

While the general physical health of this group of patients has been excellent, two have required help with emotional disorders and one of these has exhibited overt psychosis. His blood phenylalanine levels over a period of several years ranged between 600 and 840 $\mu\text{mol/L}$. Whether this observation is related to hyperphenylalaninemia is open to question and requires additional study. No associated patterns of mental illness in other family members was found.

The findings in this investigation were surprising to us. The lack of any relationship between intellectual achievement and blood phenylalanine levels was unexpected. Twelve of the 16 patients have constantly had blood phenylalanine levels above the recommended treatment ranges for classic PKU and yet did not exhibit any of the problems seen in untreated patients with PKU. Krause et al¹⁶ have reported that even small elevations of blood phenylalanine levels are associated with computerized electroencephalographic changes and slowed reaction time in certain psychoeducational activities. Despite the fact that the blood phenylalanine levels in our patients are significantly higher than those reported by Krause et al, the patients in the present study were found to be progressing well in school and seem normal with regard to intellectual achievement. Our data support the conclusion that there is no evidence to support dietary intervention in the milder forms of hyperphenylalaninemia.

One word of caution, however, is necessary in regard to such patients. The female patients with levels of phenylalanine recorded in Table 1 are at risk for anomalies in their future offspring. There is a significant maternal-to-fetal gradient of 90 to 180 $\mu\text{mol/L}$ for phenylalanine. A maternal level of 720 $\mu\text{mol/L}$ may be as high as 900 $\mu\text{mol/L}$ in the fetus. Therefore, it is imperative to follow up such patients so that pregnancy can be planned in conjunction with a phenylalanine-restricted diet.

This study was supported in part by contract NO1-HD0-4-3807 from the National Institute of Child Health and Human Development, the National Institutes of Health, Bethesda, Md (Dr Koch).

The Adolescent Heterosexual Relationship and Its Association With the Sexual and Contraceptive Behavior of Black Females

Robert H. DuRant, PhD, Susan Jay, MD

• We tested the hypothesis that the nature of the heterosexual relationship would be associated with the contraceptive and sexual behavior among three groups of females: those with a boyfriend who agreed to be interviewed ($n=31$); those whose boyfriends refused to be interviewed ($n=38$); and those without a single identifiable boyfriend ($n=44$). A pretested questionnaire was administered to a random sample of 113 black females aged 12 to 18 years from a lower socioeconomic population. The three groups did not differ in age, Tanner stage, previous pregnancies, or in demographic variables. Females with boyfriends were more likely than others to be currently sexually active. Overall, 47.8% of the sample was sexually active. Females whose boyfriends were interviewed were more likely to feel that having a baby would ruin their life. Among sexually active females ($n=54$), a higher percentage of females

whose boyfriends were interviewed (90%) were currently using a prescription method of birth control and demonstrated higher previous contraceptive compliance. There were no differences between the groups with boyfriends in the degree that the females felt their boyfriends supported their use of birth control; those without boyfriends perceived less support. Six months after the initial interview, a higher percentage of sexually active females had a boyfriend as compared with other subjects. Although the 31 females and their boyfriends differed in the mean scores of several sexual behavior and attitude scales, the girls' and their boyfriends' scores on these scales were moderately correlated. These findings suggest that the nature of the heterosexual relationship may influence both the sexual and the contraceptive behavior of black female adolescents.

(AJDC. 1989;143:1467-1472)

During the last 2 decades much of the research directed at the problems of adolescent sexuality, contraceptive behavior, and unwed pregnancy has been conducted outside the social context in which these problems normally occur.¹ Instead of examining these behaviors in terms of the dynamics of interpersonal and sexual relationship development, investigators have tended to study various structural, social, psychological, and demographic factors thought to be predictive of premarital coital and contraceptive behavior by evaluating samples of predominantly older adolescent females. Until recently peer and friendship networks were rarely studied, al-

though it was assumed that such relationships were important in adolescent sexual socialization.

Studies from the peer reference group literature have found that as children progress into adolescence, parental influences on sexual behavior tend to decrease and peer reference group influences tend to become increasingly important.^{2,3} These studies have generally found a strong, positive relationship between adolescents' and their peers' sexual attitudes and behaviors.^{4,5} Billy et al⁵ reported that after race and school grade were controlled, males neither influenced one another's sexual behavior nor selected each other as friends on the basis of having or not having sexual intercourse. There was a relationship between the sexual behavior of adolescent females and their friends. In follow-up studies on a separate sample, Billy and Udrez⁶ and Billy et al⁷ found no similarity in sexual behavior between adolescents and their same-sex friends for black males or females. Only white

adolescents established same-sex best friendships based on similarities in sexual behavior.

One unanswered question is: what impact does the adolescent female boyfriend have on her sexual attitude and behavior? As a relationship develops, the girl's boyfriend may evolve into the most significant reference individual in the adolescent female's life with regard to her sexual and contraceptive behavior.^{6,8} This may be especially true for black females, who are influenced less than white males or females by same-sex friends.^{6,7} Although the male partner is very important in the dynamic social process that results in adolescent pregnancy, there is little information regarding the effect of the male partner on sexual and contraceptive behavior. We have previously hypothesized that the establishment of a long-term monogamous relationship will result in changes in both sexual attitudes and behavior.^{8,10} As the length of time of the heterosexual relationship increases, there will be a corresponding increase in the frequency of sexual intercourse and more consistent use of birth control.

The purpose of this study is to describe the sexual and contraceptive behavior of three groups of black female adolescents with different heterosexual relationships. We also describe the similarities and differences in the sexual and contraceptive behavior of the female subjects and their boyfriends.

SUBJECTS AND METHODS

Sample

The Children and Youth Project for the State of Georgia, Augusta, provides comprehensive health care to children and adolescents residing in six low-income housing projects at no cost to the patients. At the time of this study, approximately 400 black female adolescents between the ages of 12 and 18 years were enrolled in the Children and Youth Project

Accepted for publication July 25, 1989.

From the Department of Pediatrics, Section of General Pediatrics and Adolescent Medicine, Medical College of Georgia, Augusta (Dr DuRant); and the Department of Pediatrics, Arkansas Children's Hospital, University of Arkansas for Medical Sciences, Little Rock (Dr Jay).

Presented to the Southern Society for Pediatric Research, New Orleans, La, February 2, 1989.

Reprints not available.

Using a random numbers table, we selected 125 of the females with the goal of enrolling a minimum of 100 subjects in the study. One hundred fifteen (92%) subjects agreed to participate in the study.

Procedures

After informed consent was obtained, a pretested questionnaire was administered to each girl by one black interviewer with a master's degree in psychology. The interviewer was masked to the purpose of the study. The questionnaire had undergone a 2-week test-retest pretest using 16 black female adolescents from the same population who were not enrolled in the study. The test-retest correlations for the various scales making up the questionnaire ranged from $r = .88$ to $r = .99$, with a mean of $r = .96 \pm .05$.

The questionnaire was divided into two sections. The first section contained demographic data and scales measuring behavior, attitudes, and knowledge concerning sexuality, pregnancy, and contraception.^{3,11-14} This section was administered verbally and scored by the interviewer. The second section contained the Nowicki-Strickland Locus of Control scale (range, 4 to 26),¹⁵ the Coopersmith Self-esteem Inventory (range, 4 to 22),¹⁶ and standardized scales measuring attitudes toward physicians (range, 0 to 7),¹¹ anomia (range, 0 to 5),¹⁷ well-being (range, 1 to 4), and future career and education plans.^{3,11} The second section of the questionnaire was self-administered. Following the completion of the second section of the questionnaire, the girls were shown photographs of females at different Tanner stages and asked to determine their own Tanner stage.¹⁸

Each girl's medical record was reviewed for various events occurring 1 year prior to her entry into the study. Information collected included previous pregnancies and their outcomes, previous contraceptive methods used, changes in methods, reported side effects from methods, noncompliance with or discontinuance of contraceptives, contraceptive failures, and number of family planning visits. These data were used to assess the validity of the girl's responses to similar items on the questionnaire.

After the interview the girl was asked permission to interview her boyfriend. If the girl's boyfriend accompanied her to the clinic, he was asked by his girlfriend to participate in the study at that time. If the female had come to the clinic alone, she was given a 3 × 5-inch card to give to her boyfriend, explaining the study and asking him to call to make an appointment. None of the girls refused permission to have their boyfriends interviewed and all reported that they gave the card to their boyfriend and requested that he participate in the study. Thirty-one of the females had boyfriends who agreed to participate in

the study and be interviewed. Thirty-eight females had one identifiable boyfriend each, but their boyfriends refused to be interviewed. Forty-four females did not have an identifiable boyfriend at the time of the interview. The 31 boyfriends who agreed to be interviewed were administered the same questionnaire as the girls by the same black female interviewer. Based on our interviews with the three groups of females and the boyfriends who agreed to be interviewed, we hypothesized that the heterosexual relationships of these three groups of black female adolescents were distinctly different from one another. This assumption directed the remaining data analysis.

Six months after the initial interview, 118 (98.3%) of the 115 girls were administered a second questionnaire assessing whether any changes had occurred in their sexual and contraceptive behavior during the 6-month period. Two girls could not be contacted for this interview. Data collected included changes in the female's relationship with her boyfriend, pregnancy and outcome of the pregnancy, contraceptive methods used and any changes in methods, noncompliance with birth control, and number of times she had engaged in coitus without using birth control. The boyfriends were not interviewed again at this time.

Statistical Analysis

Data from the total sample ($n = 113$) were analyzed with χ^2 , analysis of variance (ANOVA) tests, Kruskal-Wallis analysis of variance tests, and Tukey multiple comparison tests. Interval data are presented as mean \pm SD. Statistical significance was considered $P \leq .05$. Mean differences in sexual attitudes and behavior between the 31 females and their boyfriends were tested with paired t tests. Although the differences between the 31 girls and their boyfriends could be tested with either t tests for two independent means or Kruskal-Wallis ANOVA, paired t tests were chosen to provide a conservative test of the hypothesis. Correlations between demo-

graphic, sexual behavior and attitudes, and sociopsychological variables measured on the 31 girls and their boyfriends were computed using Pearson's r and Kendall's τ correlation coefficients.

RESULTS

The three groups of females did not differ ($P > .05$) in age, education, postmenarchial age, or in any demographic variables (Table 1). However, the three groups of females differed significantly ($P \leq .005$) in their sexual behavior (Table 2). Although the two groups of subjects with boyfriends did not differ in the percentage who had ever been sexually active, both groups had higher rates of previous sexual activity than the group of females with no boyfriend. Only 25% of the subjects with no current boyfriend had ever engaged in coitus. Even though the two groups of subjects with boyfriends did not differ in the mean number of months they had been dating (Table 1), a significantly higher percentage of the girls whose boyfriends agreed to be interviewed were currently sexually active than the females whose boyfriends refused to be interviewed (Table 2). These findings support the assumption that these three groups of females differed in their heterosexual relationships.

The females whose boyfriends were interviewed and those without boyfriends had stronger negative feelings ($P \leq .0118$) about the possibility of having a baby than the girls whose boyfriends refused to be interviewed (Table 3). The three groups did not differ in the other scales measuring attitudes and knowledge concerning birth control or pregnancy.

Females without a boyfriend had sig-

Anomia	2.4 \pm 1.3	2.3 \pm 1.7	2.8 \pm 1.4	...

nificantly higher ($P \leq .05$) external locus of control than females with a boyfriend (Table 3). Females whose boyfriends refused an interview had slightly higher self-esteem, but the differences were not statistically significant ($P = .06$). The three groups did not differ on any other social psychological variable.

Among subjects who had ever engaged in coitus, subjects whose boyfriends had been interviewed were using more effective contraceptive

methods than were reported by the other two groups, and stated that their current contraceptive use was related to planning to continue coitus (Table 4). Both groups of females with boyfriends reported higher boyfriend support of their use of birth control than sexually active subjects without one identifiable boyfriend. More of the subjects whose boyfriends refused an interview had been noncompliant with their birth control during the previous 12 months than

the other two groups.

Only 64.5% and 57.9% of the two groups of females with boyfriends had a current boyfriend at the 6-month follow-up (Table 5). However, significantly more of the girls whose boyfriend had been interviewed had the same boyfriend at the 6-month follow-up. Twenty-two percent of females without a boyfriend at the initial interview reported steady boyfriend 6 months later. When controlling for previous sexual activity significantly more of the sexually active subjects in all three groups had either the same or a new boyfriend at the 6-month follow-up than females who had initially reported never engaging in coitus (Table 6).

When controlling for previous sexual activity at the 6-month follow-up, the three groups did not differ significantly in the contraceptive methods used, contraceptive compliance, or the number of times they had engaged in unprotected coitus during the previous 6 months.

Among females whose boyfriend agreed to be interviewed ($n = 31$), considerable variation was found in their sexual and contraceptive behavior, knowledge, and attitudes. The males were significantly older and had completed more school grades than their girlfriends (Table 7). The females reported using birth control more often than was reported by their boyfriend and felt more pressure from their partners not to use birth control than was expressed by the males. The males reported first engaging in coitus at an earlier age, a greater coital frequency, larger number of sexual partners, and more pregnancy scares than their girlfriends (Table 7). The males also felt more positive about their girlfriends becoming pregnant and having a baby than was expressed by the females.

Although males and females differed in the mean scores of several attitudinal and behavioral variables, a number of the scales measured in the females were correlated with their boyfriend scores. The responses of the female and their boyfriends to the level of effectiveness of the birth control they used, coital frequency, number of sexual partners, and number of times pregnant or got a girl pregnant were moderately positively correlated with one another (Table 8). The males' and females' att

*One additional pregnancy occurred in a subject who was not sexually active at the pretest.

tudes toward becoming pregnant and having a baby were also moderately correlated. However, the males' and females' responses to the frequency with which they engaged in coitus without using birth control was inversely correlated.

Among the social psychological variables, the females' self-esteem and anomia were inversely correlated with their boyfriends' scores. None of the other social psychological, attitudinal, or knowledge scales were significantly correlated.

We attempted to determine whether characteristics of the heterosexual relationship were associated with the sexual and contraceptive behavior of a sample of black female adolescents. Previous theoretical and empirical work suggest that the establishment of a long-term monogamous relationship will result in changes in both sexual and contraceptive attitudes and behaviors by adolescents.⁸⁻¹⁰ When an unmarried female adolescent first becomes sexually active, she usually does not accept her identity as a sexually active person. This incongruence between the adolescent's premarital sexual standards and her actual sexual behavior results in infrequent or sporadic sexual intercourse and a decreased chance that she will rationally consider the risk of pregnancy. The resolution of the incongruence between sexual values and behavior often occurs over time after the establishment of a monogamous heterosexual relationship. A stable monogamous relationship provides a rationale for coitus, creating a congruence between premarital sexual standards and behavior, and leading to an increase in acceptance of continuing coitus. With this change in sexual identity, the frequency of intercourse will increase, resulting in a heightened awareness of the possibility of pregnancy.⁸⁻¹⁰

Even if a female adolescent possesses a heightened perception of her risk of pregnancy following unprotected coitus, her use of birth control will partly depend on her partner's attitude toward contraception.^{8,10} Scales¹⁹ suggests that, because of a difference in sex roles, male adolescents tend to have more power in their sexual relationship than their female partners. This power differential can lead to pressure for the female to engage in coitus and adopt the male's lack of consideration for birth control.²⁰⁻²² In support of this proposition, Jorgensen et al²³ found that female adolescents who reported less decision-making power over sexual issues in their relationships engaged in a greater frequency of sexual intercourse than those who perceived themselves as having relatively more control.

Based on interviews with both the female and male adolescents in our study sample, we hypothesized that the

females were involved in three distinctly different types of heterosexual relationships. Thirty-one subjects had boyfriends who agreed to undergo an extensive interview about their sexual

and contraceptive behavior and attitudes. These male and female adolescents reported to us that they communicated in a more open manner about their sexual relationships than was reported

by the other subjects, and the males exhibited a greater willingness to comply with their partners' request to be interviewed. In contrast, 38 females had one identifiable boyfriend each, all of whom refused their partner's requests to be interviewed. Although each of these females expressed a willingness for their boyfriends to participate in the study, they all reported a lack of open communication with their boyfriends about sexually related issues. In contrast with Jorgensen et al,² but in support of our previous hypotheses,⁸⁻¹⁰ fewer of the females in this group were currently sexually active than in the group of females whose boyfriends agreed to be interviewed. The third group of 44 subjects either did not have a boyfriend at the present time or could not identify one steady sexual partner. However, 22% of this group had steady boyfriends at the 6-month follow-up.

The females with boyfriends who agreed to be interviewed expressed more negative feelings about the possibility of having a baby, higher previous contraceptive compliance, used more effective contraceptive methods at the time of the interview, and were more likely to state that their use of birth control was due to their plans to continue their monogamous sexual relationship. These findings support the hypothesis that the character of the heterosexual relationship may be associated with the black female adolescents' sexual and contraceptive behaviors and attitudes. In contrast with Scales,¹⁹ these differences between the two groups of females with boyfriends were not due to their perception of their boyfriends' support of their use of contraception, the length of time they had been dating their boyfriends, the degree they felt in control of their own life or their attitudes and knowledge about birth control. The mechanism for these differences may lie with other factors associated with the stability of these subjects' heterosexual relationships.⁸⁻¹¹ At the 6-month follow-up, significantly more of the females whose boyfriends had been interviewed had the same boyfriends. Although we do not know why a greater proportion of these females maintained a stable relationship with their boyfriends, this group exhibited more responsible contraceptive behavior. Perhaps the longer the couple stays

together, the more likely they will be to communicate openly about sexually related issues. This increase in communication may result in the female adolescent feeling more comfortable with her decision to use contraception.⁸⁻¹⁰

A second objective of this study was to compare the 31 females' sexual and contraceptive behavior and attitudes with the behavior and attitudes of their boyfriends. In agreement with Freeman et al.,²⁰ the males reported more risk taking in their sexual and contraceptive behavior than their girlfriends. We also found that the females expressed feeling more pressure from their boyfriends not to use birth control than the males expressed they felt from their girlfriends, which supports the conclusions of both Scales¹⁹ and Jorgensen et al.²³ Males may also feel more positive about their girlfriends becoming pregnant and having a baby than was reported to be felt by the females. These gender differences in attitudes about having a baby are significant, considering that the self-esteem scale scores for males and females were moderately inversely correlated.

These data suggest that the risk of poor contraceptive behavior would be greatest among those couples where the male has a higher self-esteem and a positive attitude toward his girlfriend having a baby, and the female has a lower self-esteem and perceives a great deal of pressure from the male not to use birth control.

Although the mean scores of several of the attitudinal and behavioral variables differed significantly between the males and females, for many of these factors the males' and females' scores were moderately correlated. For example, although the males had less negative attitudes about the possibility of their girlfriends becoming pregnant and more positive attitudes toward their girlfriends having a baby, the couples' scores on these scales were moderately positively correlated. These findings suggest that the establishment of these relationships may have been partly based on these adolescents' similarity in attitudes and behavior.⁶ The longer the

relationship existed, the more opportunity the couples had to discuss their attitudes and beliefs about sex and birth control, and the more likely that congruence would occur in their sexual attitudes and behaviors.⁸⁻¹⁰ Billy et al.^{6,7} have reported that they were unable to find any similarity in sexual behavior between black adolescent males and females and their same-sex friends, and concluded that friendship choices were not based on sexual behavior. In comparison with Billy et al.,^{6,7} our findings of a moderate level of similarity in sexual attitudes and behavior suggest that black adolescent heterosexual relationship choices may be based partly on sexual attitudes and behaviors.

In conclusion, our data support the assumption that characteristics of the heterosexual relationship are associated with the sexual and contraceptive behavior of some black female adolescents. Although our sample was representative of the population from which it was drawn, the fact that the target group was from a black lower socioeconomic population from a southeastern city limits the national generalizability of the findings. However, this study reinforces the need for clinicians to inquire about the characteristics of an adolescent's sexual relationship during contraceptive counseling. Information such as the length of the relationship, number of sexual partners, frequency of sexual intercourse, the degree the couple communicates about their sexual relationship and contraceptive use, and the female's perception of her boyfriend's support of her use of birth control may be helpful indicators of the sexually active female's poor contraceptive behavior. Our findings also suggest that future research directed at adolescent sexuality, contraceptive behavior, and unwed pregnancy should continue to focus on the dynamics of interpersonal and sexual relationship development.

about the award-winning
Adolescent Wellness Program

When I was a child there was no Orimune®

Proven in Millions of US Patients

ORIMUNE was the first live, oral, trivalent polio vaccine. No other oral polio vaccine has done more to help eradicate wild poliovirus in the US. Over 500 million doses have been distributed to date.

Proven Safety* Record

Lederle takes every precaution during production and testing to ensure the safety of ORIMUNE. This dedication is evident by our 27-year safety record.

Uninterrupted Supply

Lederle has consistently met the nation's needs for oral polio vaccine for about 27 years. In fact, when all other US manufacturers discontinued the production of oral polio vaccine, Lederle has remained committed to this essential product and to the health of America's children.

Available in Single-Doses

ORIMUNE is available in convenient, unit-dose DISPETTES® to help assure dosage accuracy and avoid the risk of contamination.

*Paralytic disease following ingestion of live poliovirus vaccine has been reported on rare occasions in individuals receiving the vaccine or in their close contacts.

Orimune®
Poliovirus Vaccine Live Oral Trivalent

Poliovirus Vaccine Live Oral Trivalent

ORIMUNE®

A Brief Summary

Please see package insert for full description, directions for use, and references.

INDICATIONS: For prevention of poliomyelitis caused by Poliovirus Types 1, 2, and 3.

CONTRAINDICATIONS: Under no circumstances should this vaccine be administered parenterally.

Administration of the vaccine should be postponed or avoided in those experiencing any acute illness and in those with any advanced debilitated condition or persistent vomiting or diarrhea.

ORIMUNE must not be administered to patients with immune deficiency diseases such as combined immunodeficiency, hypogammaglobulinemia, and agammaglobulinemia. Further, ORIMUNE must not be administered to patients with altered immune states, such as those occurring in thymic abnormalities, leukemia, lymphoma, or generalized malignancy or by lowered resistance from therapy with corticosteroids, alkylating drugs, antimetabolites, or radiation. ORIMUNE should also not be given to members of a household in which there is a family history of immunodeficiency until the immune status of all members is determined to be normal. All persons with altered immune status should avoid close household-type contact with recipients of the vaccine for at least six to eight weeks. Inactivated poliovirus vaccine (IPV) is preferred for immunizing all persons in the above described circumstances.

WARNINGS: Under no circumstances should this vaccine be administered parenterally.

Administration of the vaccine should be postponed or avoided in those experiencing any acute illness and in those with any advanced debilitated condition or persistent vomiting or diarrhea.

Other viruses (including poliovirus and other enteroviruses) may interfere with the desired response to this vaccine, since their presence in the intestinal tract may interfere with the replication of the attenuated strains of poliovirus in the vaccine.

PRECAUTIONS: Preliminary data indicate that immune globulin (Human) (IG) does not appear to interfere with immunization with poliovirus vaccine live oral trivalent (OPV). However, until more data are available, it would seem prudent not to administer OPV shortly after IG, unless such a procedure is unavoidable, for example, with unexpected travel to or contact with epidemic areas or endemic areas. If OPV is given with or shortly after IG, the dose should probably be repeated after three months if immunization is still indicated.

The vaccine is not effective in modifying or preventing cases of existing and/or incubating poliomyelitis.

NATIONAL CHILDHOOD VACCINE INJURY ACT OF 1986 (as amended in 1987)

Manufacturer and lot number of vaccine administered must be recorded by health care provider in vaccine recipient's permanent record, along with date of administration and name, address, and title of person administering vaccine.

Health care provider must report to a health department or to the FDA the occurrence following immunization of any event set forth in the Vaccine Injury Table including: paralytic poliomyelitis—in a nonimmunodeficient recipient within 30 days of vaccination—in an immunodeficient recipient within 6 months of vaccination; any vaccine-associated community case of paralytic poliomyelitis; or any acute complication or sequela (including death) of above events.

Use in Pregnancy: Pregnancy Category C: Animal reproduction studies have not been conducted with Poliovirus vaccine live oral trivalent. It is also not known whether OPV can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity.

Although there is no convincing evidence documenting adverse effects of either OPV or IPV on the developing fetus or pregnant woman, it is prudent on theoretical grounds to avoid vaccinating pregnant women. However, if immediate protection against poliomyelitis is needed, OPV is recommended. (See **CONTRAINDICATIONS** and **ADVERSE REACTIONS**.)

ADVERSE REACTIONS: Paralytic disease following the ingestion of live poliovirus vaccines has been, on rare occasion, reported in individuals receiving the vaccine (see, for example, **CONTRAINDICATIONS**), and in persons who were in close contact with vaccinees. The vaccine viruses are shed in the vaccinee's stools for at least six to eight weeks as well as via the pharyngeal route. Most reports of paralytic disease following ingestion of the vaccine or contact with a recent vaccinee are based on epidemiological analysis and temporal association between vaccination or contact and the onset of symptoms. Most authorities believe that a causal relationship exists. Prior to administration of the vaccine, the attending physician should warn or specifically direct personnel acting under his authority to convey the warnings to the vaccinee, parent, guardian, or other responsible person of the possibility of vaccine-associated paralysis, particularly to susceptible family members and other close personal contacts.

The Centers for Disease Control report that during the years 1973 through 1984 approximately 274.1 million OPV doses were distributed in the US. During this same period, 105 vaccine-associated cases were reported (1 case per 2.6 million doses distributed). Of these 105 cases, 35 occurred in vaccine recipients (1 case per 7.8 million doses distributed), 50 occurred in household and nonhousehold contacts of vaccinees (1 case per 5.5 million doses distributed), 14 occurred in immunodeficient recipients or contacts, and 6 occurred in persons with no history of vaccine exposure, from whom vaccine-like viruses were isolated.

Thirty-three (94%) of the recipient cases, 41 (82%) of the contact cases, and 5 (36%) of the immune deficient cases were associated with the recipient's first dose of OPV. Because most cases of vaccine-associated paralysis have occurred in association with the first dose, the CDC has estimated the likelihood of paralysis in association with first v subsequent doses of OPV, using the number of births during 1973-1984 to estimate the number of first doses distributed, and subtracting this from the total distribution to estimate the number of subsequent doses distributed. This method estimates a frequency of paralysis for recipients of 1 case per 1.2 million first doses v 1 case per 116.5 million subsequent doses; for contacts one case per 1 million first doses v 25.9 million subsequent doses; with an overall frequency of 1 case per 520,000 first doses v 1 case per 12.3 million subsequent doses.

Other methods of estimating the likelihood of paralysis in association with OPV have been described. Because the number of susceptible vaccine recipients or contacts of recipients is not known, the true risk of vaccine-associated poliomyelitis is impossible to determine precisely.

When the attenuated vaccine strains are to be introduced into a household with adults who have not been adequately vaccinated or whose immune status cannot be determined, the risk of vaccine-associated paralysis can be reduced by giving these adults one dose of IPV per month for three months before the children receive Poliovirus vaccine live oral trivalent ORIMUNE. The children may receive the first dose of ORIMUNE at the same visit that the adult receives the third dose of IPV. The CDC reports that no paralytic reactions to IPV are known to have occurred since the 1955 cluster of poliomyelitis cases caused by vaccine that contained live polioviruses that had escaped inactivation.

The ACIP states: "Because of the overriding importance of ensuring prompt and complete immunization of the child and the extreme rarity of OPV-associated disease in contacts, the Committee recommends the administration of OPV to a child regardless of the poliovirus-vaccine status of adult household contacts. This is the usual practice in the United States. The responsible adult should be informed of the small risk involved. An acceptable alternative, if there is a strong assurance that ultimate, full immunization of the child will not be jeopardized or unduly delayed, is to immunize adults according to the schedule outlined above before giving OPV to the child."

The ACIP has concluded that "Oral polio vaccine remains the vaccine of choice for primary immunization of children."

State-of-the-Art Reconstructive Surgery for Bladder Exstrophy at The Johns Hopkins Hospital

John P. Gearhart, MD, Robert D. Jeffs, MD

• **Bladder exstrophy is a congenital anomaly that has been difficult to correct. Advances in reconstructive surgery, some of which have originated at The Johns Hopkins Hospital, Baltimore, Md, have impacted on the care of these patients. We reviewed the progress made in patient care and the results of state-of-the-art treatment.**

(AJDC. 1989;143:1475-1478)

Reconstructive surgery for serious congenital anomalies has shown tremendous advances in the 100 years since Johns Hopkins endowed the hospital that bears his name. Bladder exstrophy is a devastating defect that illustrates this progress in treatment. The advance was given impetus by Hugh Hampton Young, the founder of the Brady Urological Institute, The Johns Hopkins Hospital, Baltimore, Md, and by other innovations from the same institution.

Early attempts at bladder closure to produce a urine receptacle failed due to dehiscence and infection or failed to produce continence. Trendelenburg,¹ in 1906, first attempted osteotomy as an adjunct to closure of the bladder, but the first sporadic success was reported by Burns² in 1924.

The lack of success in reconstruction led to many alternatives for urinary control, beginning with Magd³ in 1894 who successfully transplanted the trigone into the rectum. The ureterosigmoidostomy performed by Coffey⁴ and improved by Nesbit⁵ and Leadbetter and Clark⁶ became a popular alternative to closure, but ascending infection, hyperchloremic acidosis, and imperfect rectal continence prevented it from being a perfect solution. Adenocarcinoma

at the ureterocolic anastomosis has also dampened enthusiasm for its use. The Boyce-Vest procedure,⁷ Heitz-Boyer-Hovalacque procedure,⁸ ileal conduit,⁹ colon conduit,¹⁰ and colocolostomy with internal diversion have all been used to treat incontinence when bladder closure was impossible or failed.

External and internal diversion may still be required for classical exstrophy when the bladder is represented by a fibrous patch and other complicating anomalies prevent closure or subsequent growth of the bladder. The ideal reconstruction is directed to accomplish closure of the abdominal wall and bladder with subsequent correction of reflux, bladder neck revision for continence, and anatomical and functional repair of the epispadias.

Young¹¹ described the first female patient with urinary continence following repair for exstrophy in 1942 at The Johns Hopkins Hospital. Failure to correct reflux, recurrent infection, and intermittent incontinence marred what had seemed at first a great success. Dees,¹² in 1949, described a method of reconstructing the bladder neck in the related condition of complete epispadias with incontinence. These early contributions might be said to have stimulated others in the field of surgery to renew efforts toward successful reconstruction in this condition.

Contributions to the management of exstrophy reads like a list of prominent urologists, pediatric urologists, and pediatric surgeons who have practiced during the last 35 years. The names of Williams and Keaton,¹³ Shultz,¹⁴ Cendron,¹⁵ Marshall and Muecke,¹⁶ Lattimer et al,¹⁷ Culp,¹⁸ Ansell,¹⁹ Johnston and Kogan,²⁰ and Chisholm²¹ are among early contributors to reconstruction and the understanding of exstrophy.

The Johns Hopkins Hospital has had special interest in the exstrophy prob-

lem during the past 15 years, with publications addressing many facets of this problem. These include factors in successful closure,²² cause of wound dehiscence,²³ muscarinic cholinergic receptors,²⁴ inheritance of classical exstrophy,²⁵ incidence of malignancy,²⁶ urodynamic assessment during bladder neck plasty,²⁷ augmentations in failed closure,²⁸ and the effect of preliminary epispadias repair on bladder volume.²⁹

Contributions from many centers have addressed epispadias repair,^{30,31} urodynamics in exstrophy,³² factors in success,³³ staged closure using colon,³⁴ and the use of artificial sphincter in exstrophy.³⁵

The great interest, the diversity of opinion, and the variety of techniques attest to the difficulty of reaching an ideal solution in every patient. In general, the advances that have led to improved success include (1) early closure with better preservation of bladder epithelium and underlying muscle, (2) technical improvement in initial closure including penile lengthening and osteotomy when necessary, (3) management of reflux after initial closure and at the time of bladder neck reconstruction, (4) staged repair allowing for bladder growth and increased volume before bladder neck plasty for incontinence, (5) Leadbetter³⁶ trigonal tubularization after ureteral relocation, (6) preliminary epispadias repair to encourage bladder adaptation at low pressure to increase volume,²⁹ and (7) adjuncts to the surgical plan and technique.³⁷

This latter category cannot be minimized when one considers that antibiotics permit the contaminated bladder to be closed as a sterile wound. Monofilament and polyglycolic acid sutures have reduced reaction in wounds and helped to prevent foci of infection and wound reaction to gut sutures. Anticholinergics, sedatives, analgesics, and im-

Accepted for publication June 2, 1989.

proved drainage techniques have kept the bladder and ureter at rest while healing occurred. Immobilization by traction or external fixation is important to maintain approximation of the anterior pelvic and fascial closure.

STAGED APPROACH

Not all patients present at birth with large bladders and an adequate phallus. The Table presents the options suggested by various ages and stages of presentation. Provision is made in the table both for the good bladder leading to successful closure and for the small bladder or others that fail to allow completion of the ideal plan.

THE ANOMALY

"In classical exstrophy no structure would seem missing," said Muecke in 1964. The defect in this anomaly (Figure) can be considered a midline separation with foreshortening of the distance between umbilicus and anal opening, with varying degrees of underdevelopment of bladder, urethra, and phallus. Classical exstrophy is the most common condition in a spectrum, ranging from penile epispadias to cloacal exstrophy. Classical exstrophy occurs in approximately 1 in 30 000 births. Shapiro et al²⁵ estimated the risk of recurrence in siblings as 1 in 300 and in offspring of patients with exstrophy as 1 in 70. Associated problems frequently seen in exstrophy are diastasis of the pubis, vesicoureteral reflux after closure, inguinal hernia, anterior displacement of the anus and sphincter mechanism, and short urethral groove. Gonadal and ductal abnormalities in both male and female patients do not appear to be part of the complex.

OSTEOTOMY

The newborn pelvis can be molded to allow midline closure of pubis and rectus fascia. This closure is sometimes difficult to hold, as the defect may be so wide that closure is difficult. Consideration should be given to each case to determine the need for osteotomy. Shultz²⁴ described the posterior iliac osteotomy, but more recently Sponseller et al³⁸ demonstrated the effectiveness of anterior transverse innominate osteotomy in promoting apposition of either initial closure or reclosure after partial or incomplete dehiscence. Firm anterior closure of the intersymphyseal bar

Management Plan for Bladder Exstrophy		
Age	Problem	Possible Solution
Initial Presentation of Patients With Bladder Exstrophy		
0-72 h	Classic exstrophy with capacity and moderate symphyseal separation; long urethral groove; mild dorsal chordee	I. Midline closure of bladder, fascia, and symphysis to level of posterior urethra; no osteotomy
0-72 h	The above findings with short urethra and severe chordee	II. Close as above, adding lengthening of dorsal urethral groove by paraexstrophy skin
0-72 h or late presentation	The above with very wide separation of symphysis or late presentation of patient (beyond 72 h to 1-3 y) for initial treatment	Iliac osteotomy and closure as in I or II
0-2 wk	Male penis duplex or extremely short	Consider female sex of rearing and closure as in I or II
0-2 wk	Very small nondistensible bladder patch	Prove by examination under anesthesia then nonsurgical expectant treatment awaiting internal or external diversion; experimental early augmentation by bowel and other material has been tried
The Incontinent Period After Initial Closure		
1 mo to 3 y	Infection with residual due to outlet stenosis	Urethral dilatation; occasional meatotomy or bladder neck revision
	Infection, grade III reflux with pliable outlet resistance	Continuous antibiotic suppression with plan for early ureteroneocystostomy
	Partial dehiscence at bladder neck or partial prolapse of bladder (both prevent bladder capacity increase)	Reclosure of bladder neck with or without osteotomy
Continence and Epispadias Repair		
2½-5 y	Closed bladder with incontinence; normal intravenous pyelogram; bladder capacity of 60 mL or more under general anesthesia; bilateral reflux; good penile size and length of urethral groove	Plan bilateral ureteroneocystostomy, bladder neck reconstruction, epispadias repair followed by 3 wk suprapubic drainage; prepare 5 wk and 2 wk before surgery with two 2-mg/kg injections of testosterone in oil
2½-5 y	As above with small bladder capacity (<60 mL)	Epispadias repair only after preparation with testosterone; bladder capacity will improve postoperatively

Continued on p 1477.

provides support and stability for the subsequent bladder neck plasty and may improve the efficacy of puborectalis and levator ani muscles.

RECONSTRUCTION OF THE BLADDER NECK

The initial stage of exstrophy management involves closure of bladder without attempts to produce continence. In the subsequent interval, free drainage aids in preventing upper tract infection and minimizes the problems from reflux. The uninfected bladder can then adapt at low pressure to urine that may accumulate at rest. The adaptation process may be encouraged by preliminary epispadias repair at 2 years of age. A capacity of 60 mL as judged under general anesthesia is desirable before proceeding with bladder neck plasty. The procedure³⁹ is a modification of the Leadbetter procedure using the Cohen⁴⁰ antireflux operation to reimplant and

relocate the ureters, followed by tubularization of the trigone and suspension of the bladder neck. Urinary diversion and minimization of bladder spasms is required to allow firm healing of the repair. Voiding trials are begun after 3 weeks of diversion. Voluntary detrusor contractions may not exist at first, gentle dilation by catheter may be required, and weeks or months may be needed to develop a useful dry interval and nocturnal control.

RESULTS

First-stage closure of the exstrophied bladder is not always successful as seen in the review of 20 patients treated for wound dehiscence after primary closure.²³ Although reclosure is possible, subsequent result of reconstruction may be disappointing. Primary closure was selected in 28 of 29 consecutive patients referred to The Johns Hopkins

Management Plan for Bladder Exstrophy (cont)		
Age	Problem	Possible Solution
	Epispadias repaired; bladder capacity greater than 60 mL	Proceed to bladder neck plasty and ureteroneocystostomy
	Epispadiac penis short with severe chordee before or after bladder neck reconstruction	Correction of chordee, lengthening of urethral groove, and epispadias repair; prepare with testosterone; consider osteotomy to aid in achieving penile length
3+ y	Complete repair of bladder, bladder neck, and epispadias with dry interval but wet pants	Patience, biofeedback, oxybutynin hydrochloride (Ditropan), imipramine hydrochloride, and time
	Above, with marked stress incontinence	Wait; may require bladder neck revision or injection
	Small-capacity bladder unchanged by time, epispadias repair, or attempted bladder neck reconstruction	Consider augmentation cystoplasty and bladder neck reconstruction; acceptance of intermittent catheterization will be necessary
3-7 y	Small bladder unsuitable for bladder neck plasty	Consider temporary diversion by colon conduit with plan for continent undiversion to bladder using bladder to form urethra and conduit for augmentation; in patients over 7 y, artificial sphincter can be considered
3-7 y	Small closed exstrophy unsuitable for bladder neck reconstruction or augmentation, or late presentation of untreated exstrophy, unsuitable for closure	Consider permanent external or internal diversion or continent urinary diversion, internal diversion direct by ureterosigmoidostomy or indirect colocolostomy; evaluate day continence of anal sphincter and nighttime seepage prior to internal diversion
5-15 y	Closed exstrophy with epispadias repaired with uncontrolled stress or dribbling incontinence	Consider revision, injection, augmentation and revision, continent urinary diversion, and artificial sphincter with omental wrap
10-20 y	Closed or diverted exstrophy with inadequate penis	Consider penile lengthening, urethral reconstruction with augmentation using free graft, pedicle grafts, and tissue transfer

Male neonate with bladder exstrophy. The umbilicus, exstrophied bladder, and complete epispadias associated with this condition are shown.

Hospital without prior treatment. One patient underwent urinary diversion because of a very small bladder. Mild bladder prolapse occurred in 2 patients who required distal revision of the closure. The remainder had satisfactory initial closure.⁴¹

Marshall and Muecke¹⁶ in 1970 reviewed 329 functional bladder closures reported in the literature between 1906 and 1966 and determined that urinary continence with preservation of renal function was achieved in only 16 (5%) of the cases.

When staged reconstruction is used similar to what is described above, better continence results are obtained as reported by Chisholm²¹ (45% continent), Ansell¹⁹ (43% continent), and Mollard⁴² (69% continent).

Oesterling and Jeffs,⁴³ in review of the The Johns Hopkins Hospital experience of 144 patients seen between 1975 and 1985, selected 50 patients who had completed staged reconstruction. Two

groups of patients were compared: group A (39 patients) had had successful initial closure while group B (11 patients) had required reclosure of the bladder after partial or complete dehiscence. Group A patients had a continence rate of 92%, while in group B only 55% became continent.

In follow-up, 88% of these groups had normal upper tracts, while 6% had persistent reflux requiring additional treatment, and 6% (3 patients) required additional treatment for hydronephrosis.

When continence is not achieved in patients with adequate bladder capacity, additional repeated bladder neck plasty may be performed or injection of polytetrafluoroethylene (Teflon) or collagen can be considered.

THE FAILED RECONSTRUCTION

When continence is not achieved, when the bladder remains too small to

proceed with bladder neck revision, or when hydronephrosis develops, techniques of salvage are well established. Twelve such patients treated at The Johns Hopkins Hospital are described by Gearhart and Jeffs.²⁸ All had augmentation cystoplasty and used intermittent catheterization; in addition, repeated bladder neck plasty in four patients, artificial sphincter in three, and Mitrofanoff procedure in one were required. Artificial sphincter is usually reserved for the older patient where omentum can be used to protect the urethra from the sphincter cuff.

LONG-TERM FOLLOW-UP

Newer techniques for correction of chordee and repair of epispadias can achieve reasonable penile length and erection. Details of epispadias repair will not be discussed in this presentation. However, all patients followed up in our local experience have erections and older patients have a normal libido. Penile length and chordee corrector are problems in some patients. Fertility in the male patient has been documented by sperm count⁴⁴ and in the report of Shapiro et al,²⁵ 38 men had fathered children. Possible injury to the ejaculatory ducts and retrograde ejaculation are a concern in the individual patient who has undergone reconstruction.

One hundred thirty-one women have delivered children²⁵ and most of these would have undergone early diversion of the urine. Reconstruction for continence should dictate delivery by cesarean section when pregnancy occurs, due to possible danger of damage to the bladder neck.

Adenocarcinoma⁴⁶ in untreated exstrophy is well known in older patients. Engel and Wilkinson²⁶ have reviewed malignancy of the bladder in exstrophy, and to date there are three patients who have developed rhabdomyosarcoma in the exstrophied bladder and two patients who underwent late closure have developed squamous cell carcinoma, while no patient who has undergone early closure has developed epithelial tumor.⁴⁶ However, long-term surveillance is mandatory in these patients.

When urinary diversion is chosen, malignancy of the bowel wall is a concern; in ureterosigmoidostomy, 10% of patients after 10 years may develop adenocarcinoma.⁴⁷

Social adjustment in a series of older patients with exstrophy reviewed by Lattimer et al¹⁷ was considered good in 13 of 17 patients. Woodhouse et al⁴⁸ found 55 of 64 patients gainfully employed and well adjusted. The recent series from The Johns Hopkins Hospital indicates that patients who underwent reconstructed exstrophy appear to have normal interactions at home and at school. Of course, long-term follow-up is required.

CONCLUSION

Early successful closure, careful management of the incontinent period, and a good technical bladder neck plasty can result in a patient with normal control and normal upper tracts. The small bladder removed from external irritation will increase in size and can be helped by preliminary epispadias repair if needed. Bladder neck reconstruction should not be attempted until the bladder reaches a capacity of 60 mL. Epispadias repair has many variations and these have not been detailed here. Lengthening of the urethral groove is often required and stimulation with testosterone is helpful in preparation for penile surgery.⁴⁹

Augmentation,²⁸ intermittent catheterization, Mitrofanoff procedure,⁵⁰ and continent diversion⁵¹ are salvage techniques that provide capacity for the

small or unusual bladder and for those whose reconstruction is unsuccessful.

This report was submitted in honor of The Johns Hopkins Hospital 1889 to 1989 centennial.

C. Warren Derrick, Jr, MD (*Contributors*); Beverly P. Wood, MD (*Section Editor*)

Figure 1.

Figure 2.

Figure 3.

A 2½-year-old white boy was seen by his pediatrician because of increasing irritability and unsteady gait. Three months prior to admission the youngster had fallen down a flight of stairs without apparent injury. Several days prior to admission, the child experienced progressive low back pain and stiffness.

The boy's medical history was remarkable for multiple episodes of oti-

tis media and upper respiratory tract infections requiring medical therapy. The patient completed a 10-day course of antibiotic therapy as recently as 1 month prior to injury.

On admission, the patient was afebrile and the results of the physical examination were normal except for a wide-base gait and pronounced lumbar lordosis. Admission laboratory values were as follows: white blood cell count, $13 \times 10^9/L$, with 0.70 polymorphonuclear leukocytes; hemoglobin level, 116 g/L; hematocrit value, 0.33; platelet count, $504 \times 10^9/L$; erythrocyte sedimentation rate (Westergren), 13 mm/h; and the complement profile was C3, 1.48 g/L, and C4, 0.28 g/L. The C-reactive protein was positive. The result of a tuberculin skin test

was negative. The results of the urinalysis were normal. Blood and urine cultures were negative.

A technetium pyrophosphate bone scan (Fig 1) and roentgenograms of the lumbosacral spine (Fig 2) were obtained. Unenhanced computed tomography was also performed (Fig 3).

Based on the roentgenographic and computed tomographic findings showing narrow disk space, and the negative cultures, a presumptive diagnosis of diskitis rather than vertebral osteomyelitis was made. Magnetic resonance imaging of the affected area showed loss of the normal disk signal intensity on T_1 images and increased signal intensity within the involved vertebral bodies on T_2 images (Fig 4). Thickening of adjacent paravertebral

Accepted for publication December 22, 1988.

Figure 4.

soft tissue was noted. Needle aspiration of the L3-4 disk space yielded normal findings. The patient was treated with ceftriaxone (50 mg/kg per day) and nafcillin (100 g/kg per day) for 2 weeks, followed by 4 weeks of oral cephalexin (100 mg/kg per day), with marked clinical improvement. One month after presentation, the patient was asymptomatic.

Diskitis is a self-limited inflammation of the intervertebral disk space that occurs primarily in children.¹⁻⁶ The peak incidence occurs at 2 to 3 years of age^{2,5,7} with girls outnumbering boys by 2 to 1.⁷ The majority of cases involve the lumbar spine.^{1,3,4,6,8,9} Although not a requirement for diagnosis,^{3,8} pathogens isolated from aspiration biopsy include *Staphylococcus aureus*^{1,3,4} or, occasionally, *Haemophilus influenzae*.⁷

In contrast to vertebral osteomyelitis, children with diskitis generally are not systemically ill.² Fever may not be present, and the total and differential white blood cell counts may be normal. Often, the only laboratory abnormality may be an elevated erythrocyte sedimentation rate.^{1-6,8}

Diskitis is a clinical diagnosis that, because of its variable presentation, requires a high index of suspicion.^{3,5,6,8} Children with diskitis frequently present with vague, low back pain and difficulty or refusal to sit up, walk, or bear weight.¹⁻¹¹ Generally, the child refuses to assume any position that flexes the spine.^{3,5,7,8} The physical examination reveals abnormal posturing with exaggerated lumbar lordosis^{2,6} or

Fig 1.—Technetium pyrophosphate bone scan showing increased uptake of isotope at L3-4.

Fig 2.—Lateral roentgenogram of the lumbosacral spine revealing narrowing of the L3-4 disk space with irregularity of the adjacent end plates.

Fig 4.—Magnetic resonance image of the affected area showing loss of the normal disk signal intensity of T₁ images.

a change in gait pattern without neurological findings.^{4,7} Percussion and/or palpation of the lumbar spine does not reliably reproduce symptoms.

Although the exact etiology of diskitis is unclear,⁸ preceding trauma may be the inciting event.^{2,5} In children, the vascular supply of the disk space branches from adjacent vessels supplying the vertebral bodies.^{2,3,5,10} Trauma with a resulting separation of the vertebral end plates and disruption of the vascular supply, in the presence of transient bacteremia, may allow the entrance of pathogens into the vertebral disk space.^{2,3,5,8} In contrast, by the third decade, the disk space is largely avascular,^{2,3} and infectious inflammation of the disk is likely the result of progressive vertebral osteomyelitis.^{1,5}

Despite various treatment modalities, ranging from total body cast immobilization to strict bedrest with or without antibiotic treatment, children have recovered without sequelae.^{1,5,8} Surgical decompression with open diagnostic biopsy is not routinely advocated.^{3,5,8} Early diagnosis is important to accurately rule out more serious and potentially treatable conditions, such as osteomyelitis, septic arthritis, tuberculosis (Pott's disease), meningitis, or spinal tumors.

The classical findings of disk space narrowing and loss of the superior vertebral notch observed on lateral spine roentgenograms may not be evident until 2 to 8 weeks after the onset of symptoms.¹⁻⁷

Technetium or gallium bone scans may provide roentgenographic evidence as early as 1 week after symptoms appear.^{5,7,12} However, the use of gallium in infants is discouraged due

to the greater radiation exposure.⁶ Additionally, normal results of gallium or technetium bone scans do not exclude diskitis.⁸

We describe a case of a patient with diskitis that was confirmed by magnetic resonance imaging. Magnetic resonance imaging distinguishes disk inflammation from pyogenic bone lesions and is rapid, accurate, and non-invasive. The role of magnetic resonance imaging will require more widespread use and clinical evaluation before becoming the radiologic procedure of choice for the diagnosis of diskitis in children.

A 4-year-old, previously well girl was admitted to an outside hospital with an acute illness consisting of abdominal pain, watery diarrhea, and nonbilious vomiting. She was presumed to have an acute gastroenteritis with dehydration. She was transferred to our institution 48 hours later after her diarrhea became bloody. The

patient's white blood cell count was $39 \times 10^9/L$ and rising, her platelet count was $90 \times 10^9/L$ and falling, and her hemoglobin level was 100 g/L and falling. Only erythematous mucosa was found at proctoscopy. Abdominal roentgenography (Fig 1) and barium enema examination (Fig 2) were performed.

Denouement and Discussion

Gastrointestinal Manifestations of Hemolytic Uremic Syndrome

Fig 1.—Plain roentgenogram of the abdomen showing no evidence of toxic megacolon, fixed loops of bowel, or intussusception.

Fig 2.—Barium enema examination shows thickened folds (arrows) representing edema and hemorrhage in the submucosa mucosal spiculation representing inflammation, and patulous terminal ileum representing ileitis.

Hemolytic uremic syndrome (HUS) is a disease of unknown origin usually occurring in children younger than 4 years. The pathologic findings resemble a microangiopathy and are associated with an angiitis and the formation of platelet thrombi resulting in the classic triad of hemolytic anemia, thrombocytopenia, and azotemia. Hemolytic uremic syndrome may belong with a continuum of disease, including thrombotic thrombocytopenia purpura. Characteristically, there is a prodromal illness that is most commonly a nonspecific gastroenteritis. This is followed in 1 to 2 weeks by the development of a variable number of presenting abnormalities, including pallor, purpura, abdominal pain, hematuria, oliguria, hematemesis, and bloody diarrhea. Therefore, HUS may be mimicked by a number of entities, including glomerulonephritis, He-

noch-Schönlein purpura, nephrotic syndrome, and myelophthisic diseases. As with our patient, HUS may occasionally mimic inflammatory bowel disease.^{1,2} More rarely, gastrointestinal presentations include toxic megacolon or rectal prolapse.³ The bowel wall thickening and "thumb printing" seen in our patient was most likely due to submucosal hemorrhage (Fig 2). During its course, HUS has diffuse manifestations reflecting widespread microangiopathy. Prominent signs of this multisystem involvement include hypertension, fluid and electrolyte imbalance, bleeding diatheses, seizures, coma, nephrotic syndrome, colitis, myocarditis, and hepatomegaly.

Our patient's normal renal function deteriorated rapidly, requiring hemodialysis management. Complete recovery occurs in 1 to 3 weeks in most

children who are medically supported, but complications can prolong this recovery period. Anuria can be successfully treated with dialysis, but some children suffer from chronic renal insufficiency. The mortality rate in the 1970s was between 10% to 20% but has decreased considerably with the more widespread use of early dialysis. Poor prognosis is related not only to the severity of the renal involvement, but also more importantly to the severity of extrarenal, especially central nervous system, involvement.

NIX[®] FOR LICE[®]

CREME RINSE

permethrin 1%

*Nix
Disp 2 fl oz
Sig. as
directed on bottle
label
Tom Smith, MD*

PEDICULICIDAL/OVICIDAL ACTIVITIES: *In vitro* data indicate that permethrin has pediculicidal and ovicidal activity against *Pediculus humanus* var. *capitis*. The high cure rate (97-99%) of Nix in patients with head lice demonstrated at 14 days following a single application is attributable to a combination of its pediculicidal and ovicidal activities and its residual persistence on the hair which may also prevent reinfestation.

INDICATIONS AND USAGE: Nix is indicated for the single-application treatment of infestation with *Pediculus humanus* var. *capitis* (the head louse) and its nits (eggs). Retreatment for recurrences is required in less than 1% of patients since the ovicidal activity may be supplemented by residual persistence in the hair. If live lice are observed after at least seven days following the initial application, a second application can be given.

CONTRAINDICATIONS: Nix is contraindicated in patients with known hypersensitivity to any of its components, to any synthetic pyrethroid or pyrethrin, or to chrysanthemums.

WARNING: If hypersensitivity to Nix occurs, discontinue use.

PRECAUTIONS:

General: Head lice infestation is often accompanied by pruritus, erythema, and edema. Treatment with Nix may temporarily exacerbate these conditions.

Information for Patients: Patients with head lice should be advised that itching, redness, or swelling of the scalp may occur after application of Nix. If irritation persists, they should consult their physician. Nix is not irritating to the eyes; however, patients should be advised to avoid contact with eyes during application and to flush with water immediately if Nix gets in the eyes. In order to prevent accidental ingestion by children, the remaining contents of Nix should be discarded after use.

Combing of nits following treatment with Nix is not necessary for effective treatment. However, patients may do so for cosmetic or other reasons. The nits are easily combed from the hair treated with Nix after drying.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Six carcinogenicity bioassays were evaluated with permethrin, three each in rats and mice. No tumorigenicity was seen in the rat studies. However, species-specific increases in pulmonary adenomas, a common benign tumor of mice of high spontaneous background incidence, were seen in the three mouse studies. In one of these studies there was an increased incidence of pulmonary alveolar-cell carcinomas and benign liver adenomas only in female mice when permethrin was given in their food at a concentration of 5000 ppm. Mutagenicity assays, which give useful correlative data for interpreting results from carcinogenicity bioassays in rodents, were negative. Permethrin showed no evidence of mutagenic potential in a battery of *in vitro* and *in vivo* genetic toxicity studies. Permethrin did not have any adverse effect on reproductive function at a dose of 180 mg/kg/day orally in a three-generation rat study.

Pregnancy: Teratogenic Effects: Pregnancy Category B: Reproduction studies have been performed in mice, rats, and rabbits (200-400 mg/kg/day orally) and have revealed no evidence of impaired fertility or harm to the fetus due to permethrin. There are, however, no adequate and well-controlled studies in pregnant women. Because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers: It is not known whether this drug is excreted in human milk. Because many drugs are excreted in human milk and because of the evidence for tumorigenic potential of permethrin in animal studies, consideration should be given to discontinuing nursing temporarily or withholding the drug while the mother is nursing.

Pediatric Use: Nix is safe and effective in children two years of age and older. Safety and effectiveness in children less than two years of age have not been established.

ADVERSE REACTIONS: The most frequent adverse reaction to Nix is pruritus. This is usually a consequence of head lice infestation itself, but may be temporarily aggravated following treatment with Nix. 5.9% of patients in clinical studies experienced mild temporary itching; 3.4% experienced mild transient burning/stinging, tingling, numbness, or scalp discomfort; and 2.1% experienced mild transient erythema, edema, or rash of the scalp.

DOSE AND ADMINISTRATION:

Adults and Children: Nix is intended for use after the hair has been washed with shampoo, rinsed with water and towel dried. Apply a sufficient volume of Nix to saturate the hair and scalp (especially behind the ears and on nape of the neck). Nix should remain on the hair for 10 minutes before being rinsed off with water. A single treatment is sufficient to eliminate head lice infestation. Combing of nits is not required for therapeutic efficacy, but may be done for cosmetic reasons or to meet school "no nit" policies. A nit comb is provided.

SHAKE WELL BEFORE USING.

HOW SUPPLIED: Nix (Permethrin) 1% (wt./wt.) Creme Rinse is supplied in plastic squeeze bottles that contain 2 fl. oz. weighing 56 g. (NDC-0081-0780-81)
Store at 15°-25°C (59°-77°F).

Partition of Nitrogen Intake and Excretion in Low-Birth-Weight Infants

Sharon M. Donovan, PhD, RD; Stephanie A. Atkinson, PhD; Robin K. Whyte, MB, FRCPC; Bo Lönnerdal, PhD

• Although nitrogen balance studies have been carried out in low-birth-weight infants, few have partitioned the nitrogen into its components. In this study, 72-hour balance studies were conducted in 24 low-birth-weight infants (gestational age, 30.7 ± 1.6 weeks; birth weight 1.36 ± 0.25 kg) fed their mothers' milk (preterm milk) or 50% preterm milk and 50% formula. Total nitrogen, nonprotein nitrogen, and whey protein intake and excretion were measured. Total nitrogen intake (preterm milk group, 452 ± 138 mg/kg per day; preterm + formula group, 406 ± 93 mg/kg per day), absorption (85%), and retention (71%) were not significantly different between groups. Intact and fragments of secretory IgA and lactoferrin were detected in soluble fecal extracts, and represented 25% and 9% of intake, respectively. Feeding preterm milk allows for nitrogen accretion similar to intrauterine growth rates for 5 weeks postnatally, and provides potentially functional proteins for the low-birth-weight infant.

(AJDC. 1989;143:1485-1491)

The early neonatal period is characterized by high nutrient requirements and immature digestive and excretory capacities. Human milk meets the nutritional needs of term infants without exceeding their physiological limitations¹; however, the premature infant has higher nutrient requirements than the term infant, coupled with less well-developed gastrointestinal functions. Therefore, the suitability of mature human milk, particularly banked human milk, as a source of energy, protein, and minerals for the premature infant has been questioned.^{2,3} Atkinson et al⁴ reported that the nitrogen content of milk from mothers delivering prematurely ("preterm milk" [PTM]) was significantly higher than the nitrogen con-

centration of term milk for the first month of lactation. Preterm milk contains higher concentrations of protein, macrominerals, energy, and electrolytes,^{4,8} which led to the speculation that the optimum food for the premature infant may be the milk of the infant's mother.^{9,10}

Nitrogen in human milk is present as protein nitrogen and nonprotein nitrogen (NPN). Protein nitrogen is derived from both casein and whey proteins and constitutes approximately 75% of the nitrogen in mature human milk.¹¹ Several whey proteins may have important functions in the suckling infant,^{12,13} including secretory IgA (sIgA), lactoferrin, lipase, and lysozyme. Each of these proteins is believed to act within the gut via different bacteriostatic or immunologic mechanisms to protect the infant, including preventing attachment of bacteria and viruses to cells within the intestine,¹⁴ sequestering of nutrients,¹⁵ or causing lysis of bacteria.¹⁶ For these proteins to be functional, they must remain intact throughout at least part of the infant's gastrointestinal tract.¹² Identification of immunologically intact sIgA, lactoferrin, and lysozyme in the feces of human milk-fed term^{15,17,18} and premature^{19,20} infants provides support for this hypothesis.

Nonprotein nitrogen is composed of a diverse group of low-molecular-weight compounds and accounts for 25% of the total nitrogen.^{11,21} The function of NPN in the nutrition of human milk-fed infants is still unclear, although nutritional and functional roles have been proposed. Urea nitrogen and free amino acids may provide nitrogen essential for synthesis of nonessential amino acids,²² whereas peptide hormones²³ and growth factors²⁴ may serve physiological rather than nutritional functions for the infant.

The goals of this study were, first, to investigate the adequacy of feeding solely PTM, compared with a combination of PTM and infant formula, on overall nitrogen retention; and second, to

quantitate and partition total nitrogen intake and excretion, as protein nitrogen (including the whey proteins) and NPN components.

PATIENTS AND METHODS

Subjects

Low-birth-weight infants ($n = 24$; 12 male, 12 female) were selected from the neonatal unit of Chedoke-McMaster Hospitals, McMaster Health Sciences Centre, Hamilton, Ontario. Infants were included in the study based on the following criteria: birth weight less than 1.8 kg, no congenital anomalies, not requiring mechanical ventilation at the time of the study, and ability to tolerate at least 150 mL/kg per day of feedings by 21 days of age. The study protocol was approved by the ethics committee of Chedoke-McMaster Hospital and was described to the parents, and signed consent was obtained. One group received only PTM and the second group received 50% PTM and 50% standard infant formula (PTM + F group) (Wyeth Ltd, Windsor, Ontario). Infants were assigned to one of two study groups depending on the ability of maternal lactation to support the needs of her infant(s). Most infants (balance 1, 5 of 6; balance 2, 3 of 5) in the PTM + F group were twins. Maternal milk production would have supported 1 infant but not 2. After the infants had been receiving full oral feeds for at least 1 week and were gaining greater than 10 g/kg per day, two 72-hour balance periods were carried out (Table 1).

Collection of Samples

Preterm milk samples were obtained from each infant's mother and were either fed fresh within 48 hours of pumping or frozen at -20°C until used. Each infant received only milk from his or her mother. During the balance study, 24-hour collections of milk were pooled, warmed to 37°C , and gently mixed. Individual feedings of formula and milk samples were measured into syringes by research staff. Formula or milk was bolus fed every 2 hours by nasogastric gavage. Urine and fecal samples were collected as previously described.⁹ Urine samples were collected using an acid-washed apparatus (made from fingers of plastic gloves and respiratory tubing) and drained into plastic containers that were subsequently refrigerated. Feces were collected in urine bags (U-bag, Hollister Ltd,

Accepted for publication August 24, 1989.

From the Department of Nutrition, University of California, Davis (Drs Donovan and Lönnerdal) and the Department of Pediatrics, McMaster University, Hamilton, Ontario (Drs Whyte and Atkinson).

Reprint requests to Department of Nutrition, University of California Davis, Davis, CA 95616.

Willowdale, Ontario). Plastic-backed ashless filter papers were placed beneath the head and posterior of the infant to collect any nitrogen losses due to regurgitation or urine leaks. All samples were stored at -20°C after collection. Stool samples were homogenized and freeze-dried prior to analysis.

Analyses

Milk, formula, urine, and stool samples were analyzed for total nitrogen, soluble nitrogen, and NPN by automated micro-Kjeldahl analysis (Tecator, Uppsala, Sweden).²⁵ The soluble fractions of PTM, formula, and rehydrated stool samples were isolated by ultracentrifugation at 189 000g for 1 hour at 4°C (Sorvall Model OT065B, Rotor AH650, Newton, Conn). Nonprotein nitrogen was determined in the soluble fractions of milk, formula, urine, and rehydrated stool samples following precipitation of proteins by the addition of an equal volume of 24% trichloroacetic acid and centrifugation at 10 000g. Urea nitrogen was determined using a modified urease-Berthelot reaction²⁶ (Sigma, St Louis, Mo). Human milk whey proteins were quantitated in the soluble fractions of PTM, urine, and fecal samples using rocket immunoelectrophoresis (lactoferrin, sIgA, serum albumin) and radial immunodiffusion (lysozyme, α -lactalbumin).²⁷ Immunoelectrophoresis was run in 0.025 mmol/L tricine buffer (pH 8.5) for 3 hours at 300 V.

To better characterize the soluble fecal fraction, crossed immunoelectrophoresis²⁷ of feces against anticolostrial whey and against antihuman serum was run on a subset of 10 infants from each dietary treatment. In this method, electrophoresis of the sample is run for 1 hour at 300 V in agarose without antibodies to separate the proteins by molecular weight. The plate is then rotated 90° and the sample electrophoresed for 3 hours at 300 V into agarose containing antibody. The location of specific proteins is determined by comparisons with plates run with purified proteins.

Proteins and peptides in soluble fecal extracts were separated by gel filtration Fast Protein Liquid Chromatography (Pharmacia Fine Chemicals, Piscataway, NJ). A sample volume of 50 μL was applied to a gel filtration column (Superose 12, Pharmacia Fine Chemicals) and eluted in 20 mmol/L ethanolamine buffer (pH 9.5) at a flow rate of 1.0 mL/min. The eluant was collected in 1-mL fractions and monitored at 280 nm.

Calculation of Results

Apparent nitrogen digestibility was calculated by the following formula: nitrogen intake minus fecal nitrogen output. Apparent nitrogen nutrition was calculated as follows: nitrogen intake minus fecal nitrogen output minus urinary nitrogen output. No adjustments were made for insensible nitrogen losses that consist mainly of cutaneous

losses.²⁸ Statistical analysis was carried out using a two-way analysis of variance, with study weight and study age as covariants.²⁹ Multiple mean comparisons were made using Duncan's Multiple Range Test and Bonferroni adjusted significance level. A value of $P < .05$ was chosen as the level of significance for both Duncan's and Bonferroni analyses. All statistical analyses were done with the Statistical Analysis System (SAS Institute, Cary, NC).

RESULTS

Infant Population

Twenty-four infants were recruited for the study. During the first balance, 18 infants received solely PTM and 6 received PTM + F. During the second balance, 9 of the original 18 PTM-fed infants received PTM again, 1 infant was switched to the PTM + F group, and 8 did not complete a second balance period.

PTM and Formula Composition

Mean nitrogen and protein concentration of PTM and formula used in this

study are presented in Table 2. Lactational day was calculated from the first day following parturition. Mean lactational day represents the mean value for the three 24-hour pooled PTM samples fed during the study period. There were no significant differences in the total nitrogen, soluble nitrogen, NPN, or urea nitrogen between PTM and the formula used. In human milk and formula samples, NPN was $19\% \pm 0.1\%$ of the total nitrogen, with urea nitrogen comprising 26% of the NPN (Table 2).

Nitrogen Intake

The distribution of nitrogen intake between the two dietary groups is shown in Fig 1. For PTM-fed infants $60\% \pm 2\%$ of the nitrogen intake was associated with human whey proteins, $20\% \pm 5\%$ with human casein, $20\% \pm 3\%$ with NPN. For infants receiving PTM + F, formula protein (bovine whey and casein) provided $41\% \pm 1\%$ of the nitrogen; human milk whey proteins, $30\% \pm 5\%$; human milk casein, $9\% \pm 2\%$;

and total NPN from formula and human milk, $21\% \pm 3\%$.

Nitrogen Balance

All infants were maintained in positive nitrogen balance (Table 3). Nitrogen intake, absorption, and retention were not significantly different between groups, with an average 85% digestibility and 71% retention. Nitrogen intake was highly correlated with nitrogen retention (milligrams per kilogram per day) in PTM-fed infants ($y = 86 + 1.1x$, $r = .98$, $P < .01$) and PTM + F-fed infants ($y = 211 + 0.74x$, $r = .97$, $P < .01$). Adjustment of nitrogen retention data by 11 mg/kg per day (previously estimated cutaneous losses²⁸) does not significantly decrease the retained nitrogen relative to intrauterine accretion rates.

Results for NPN and urea nitrogen intake and excretion are shown in Table 4. There were no significant differences in NPN or urea nitrogen intake between the groups. Urinary nitrogen and NPN were both decreased from balance period 1 to balance period 2 ($P < .05$). Balances for NPN and urea nitrogen were not calculated since it is impossible to determine whether the excreted NPN or urea nitrogen arose from the diet or as a product of protein metabolism.

Whey Protein Intake and Excretion

Intake and excretion data for the human milk whey proteins are presented in Table 5. Immunologically intact α -lactalbumin was not detected in feces of any infant. Due to the large degree of interinfant variability, no significant differences in the amounts of whey protein excretion were observed between the groups. Serum albumin was detected in the feces of 38% of the infants and accounted for 0.5% and 0.6% of the intake in PTM and PTM + F groups, respectively. Although total lactoferrin and lysozyme excretion were not significantly different between the two groups, when excretion is expressed as percentage of intake, the PTM + F group excreted a significantly greater proportion of lactoferrin (13% vs 5%) and lysozyme (18% vs 3%) than infants fed PTM alone.

Fecal Nitrogen Excretion

The different components of the fecal nitrogen are shown in Fig 2. Insoluble

nitrogen excretion was significantly greater in the PTM + F group. Excretion of nitrogen associated with soluble proteins was not significantly different between the two dietary groups. The insoluble fraction contains particulate matter, including sloughed intestinal and microbial cells. Nonurea NPN excretion was not significantly different between the two groups, but slightly less nitrogen was associated with fecal urea in the PTM + F-fed infants (14% vs 20%). The quantifiable components of

the fecal soluble protein fraction are shown in Fig 3. Fecal soluble nitrogen (total soluble nitrogen minus NPN) included several whey proteins—lactoferrin, sIgA, lysozyme, and serum albumin as well as other soluble proteins. Lactoferrin and sIgA together accounted for an average of 52% and 72% of the soluble proteins in feces of PTM-fed and PTM + F-fed infants, respectively.

Using crossed immunoelectrophoresis, four whey proteins were detected in the feces of all 10 infants studied, corre-

sponding to lactoferrin, serum albumin, α_1 -antitrypsin, and sIgA (Fig 4). Three to four proteins were detected in the feces using the antibody against human serum proteins. Two were identified as α_1 -antitrypsin and serum albumin. A third high-molecular-weight serum protein was detected, possibly IgG. No other immunologically intact whey or serum proteins were detected by this method. Gel filtration chromatography of the soluble fecal extract using Superose 12 Fast Protein Liquid Chromatography revealed significant amounts of intact lactoferrin and sIgA in both PTM-fed and PTM + F-fed infants (Fig 5). In addition, large amounts of peptides whose molecular weights were less than 10 000 d were found in the feces of both groups of infants. The inset in Fig 5 shows the chromatographic separation of PTM on Superose 12 for comparison to the fecal extracts.

COMMENT

When comparing infants fed human milk with those receiving infant formula, one must consider the differences in nitrogen composition between bovine and human milk. Human milk consists of predominantly whey proteins,¹¹ several of which appear to be resistant to digestion within the gastrointestinal tract of both term¹⁷ and premature infants.¹⁹ In addition, 25% of the nitrogen in human milk is found as NPN.²¹ Partial utilization of NPN by the human infant has been demonstrated as retention of labeled urea nitrogen.^{22,30-32} Thus, while a proportion of the immune protein-bound amino acids in human milk may not be physiologically available to the infant for protein synthesis,¹² it is likely that some nitrogen from small-molecular-weight compounds may be retained by the infant.

In this study the effect of feeding solely PTM or a combination feeding of 50% PTM and 50% standard infant formula (PTM + F) on the intake and excretion of various nitrogen components was examined. There were no significant differences in overall nitrogen intake and excretion between the infants fed PTM or PTM + F. Nitrogen absorption from both diets was similar to that previously reported for premature infants fed mature human milk or standard infant formula.³³⁻³⁵ The goal for nitrogen accretion for premature infants is often set at levels that will allow growth and accretion

rates similar to those occurring in utero. Between 18 and 40 weeks of gestation, the nitrogen concentration in the fetus

rises linearly.³⁶ Based on these data and fetal body weights,³⁷ Jackson et al³⁸ calculated the nitrogen content of fetuses

Fig 2.—Composition of fecal nitrogen excretion in preterm milk (PTM)- and PTM and formula (PTM + F)-fed infants. Results are expressed as a percentage of total nitrogen excretion. NPN indicates nonprotein nitrogen.

Fig 3.—Components of the fecal soluble protein (soluble nitrogen minus nonprotein nitrogen [NPN]) fraction of infants receiving preterm milk (PTM) or PTM and formula (PTM + F). HSA indicates human serum albumin.

Fig 4.—Crossed immunoelectrophoresis of fecal extracts in gels containing antiserum and anticolostal whey. Peaks were identified as secretory IgA (sIgA), lactoferrin (Lf), serum albumin (SA), and α_1 -antitrypsin (α_1 -AT) by using purified proteins as standards.

growing along the 10th, 50th, and 90th percentiles. A comparison between the mean nitrogen accretion for our study infants and fetuses of similar postconceptual age growing at the 50th percentile is shown in Table 6. During balance period 1, all infants retained nitrogen at or above the 50th percentile for infants in utero. However, during balance period 2, nitrogen accretion for the PTM + F-fed infants dropped off to a rate similar to infants at the 10th percentile. Although the mean nitrogen retention was not statistically different between groups, the balance period 2 infants in the PTM + F group had the lowest mean total nitrogen intake (per kilogram of birth weight) and a 5% increase in mean fecal nitrogen excretion over the other groups. These differences may account for the lower nitrogen accretion in these infants.

There were no significant differences in intake of NPN or intake and excretion of urea nitrogen between the dietary groups, which reflects the similar nitrogen distribution in the PTM and infant formula (Table 2). This infant formula is based on electrodialyzed whey, which contains a relatively high proportion of NPN.³⁸ The significantly lower urinary NPN excretion in the PTM + F-fed infants in balance period 2 reflected the lower urinary total nitrogen excretion in this group and was associated with the lower nitrogen intake (per kilogram of birth weight). Although calculating NPN or urea nitrogen "balance" will not reveal anything about the true metabolic fate of the ingested NPN or urea nitrogen since these compounds are endogenously produced during protein catabolism, it is interesting to note that for balance 2, PTM-fed infants averaged a "positive" NPN retention.

Previous studies utilizing urea labeled with ¹⁵N (¹⁵N-urea) as a marker of dietary urea have demonstrated that animals^{39,40} and humans^{22,41} maintained on either low-protein diets or purified essential amino acids will utilize supplementary urea nitrogen. Several investigators^{22,30,32,42} have studied the bioavailability of dietary urea in both term^{22,30,32} and premature⁴² infants. The retention of ¹⁵N-urea ranged from 13% to 43% of the administered dose in these studies. There was no significant difference in retention between term infants fed formula³⁰ or human milk.³¹ However, pre-

mature infants⁴² and infants recovering from malnutrition²² or illness³² retained more of the administered ¹⁵N-urea than normal term infants.^{30,31} Rose and Dekker³⁹ demonstrated in the 1950s that the utilization of NPN as a source of nitrogen decreased when dietary protein was adequate. Therefore, the tendency for premature or compromised infants

to retain more urea nitrogen may be a reflection of their higher nitrogen requirements (per kilogram of birth weight).

Human milk whey proteins serve nutritional and functional roles for the infant. Secretory IgA, lactoferrin, and lysozyme have been postulated to contribute to the human milk-fed in-

Fig 5.—Superose 12 Fast Protein Liquid Chromatography separation of the soluble fecal extracts from infants receiving preterm milk (PTM) and PTM and formula (PTM + F). Inset shows chromatographic separation of preterm human milk. Lf indicates lactoferrin.

fant's resistance to gastrointestinal and respiratory tract infections.^{48,44} Although the persistence of lactoferrin, sIgA, and lysozyme through the gastrointestinal tract of the infant is well documented, and has been demonstrated in both term^{18,17,18} and premature^{19,20} infants, one of the aims of the present study was to better characterize the contribution of the whey proteins to overall nitrogen intake and fecal excretion. The contribution of human milk whey proteins to overall nitrogen intake reflects the composition of the infants' diet, constituting 60% of the nitrogen intake in PTM-fed infants and 30% in PTM + F-fed infants. We attempted to quantitate cow's milk whey protein intake and excretion using antibodies against bovine whey proteins. However, due to the extensive modification of the proteins during formula manufacturing, they were no longer recognizable by the antibodies.

The presence of intact lactoferrin and sIgA in fecal extracts from both PTM-fed and PTM + F-fed infants was demonstrated by gel filtration chromatography (Fig 5). In addition, a large amount of peptides with molecular weight greater than 10 000 d was observed in both sets of infants. Fecal proteins are generally quantitated by either immunoelectrophoresis^{17,19} or enzyme-linked immunosorbent assay²⁰; however, each of these assays measures only whether the protein is "immunologically" intact and not if it is structurally intact. When quantitating fecal lactoferrin by rocket immunoelectrophoresis, we observed "double rockets" in some samples. If lactoferrin were partially degraded, yet still intact enough to be recognized by the antibody, the smaller fragments would migrate farther than the intact molecule in the electrophoretic field, re-

sulting in two rockets. No double rockets were observed for milk lactoferrin, fecal or milk sIgA, or serum albumin. Recent investigations in our laboratory⁴⁶ have demonstrated that "half-lactoferrin," produced by proteolytic digestion at low pH, is immunologically reactive. In addition, the half-lactoferrin showed similar binding to its intestinal lactoferrin receptor as intact lactoferrin. Thus, even after partial digestion, ie, cleavage into two iron-binding fragments, lactoferrin retains enough structural integrity to interact with the receptor and potentially serve a functional role in vivo. Larger fragments of lactoferrin in the stool of preterm infants have been reported by Goldman et al.⁴⁶ However, in their study sodium dodecyl sulfate, a denaturing agent that dissociates all peptides from each other, was used, while we used gel filtration and nondissociating conditions. It has been shown that the two larger fragments of transferrin⁴⁷ and lactoferrin⁴⁸ self-associate. Therefore it is likely that lactoferrin in the stool is present both as large fragments and in intact form.

Whey proteins in the feces may arise from several sources: undigested milk proteins, endogenous synthesis and secretion into the intestinal lumen, or by leakage into the intestine from serum. Endogenous secretion of sIgA and lactoferrin in formula-fed term^{44,49} and premature²⁰ infants has been reported to be low. In term infants, no fecal sIgA was detected in formula-fed infants less than 3 weeks of age.⁴⁴ Spik et al⁴⁹ detected a constant value of 0.5 mg of lactoferrin every 24 hours in the feces of formula-fed term infants, probably representing endogenous synthesis. The infants in our study were excreting between 30 and 45 mg of lactoferrin every 24 hours,

which is well above this level. Premature infants receiving formula excreted only 0.5% to 3.0% of the levels of "protective" proteins as infants receiving fortified human milk.²⁰ These studies suggest that the role of endogenous secretion in contributing to fecal proteins is limited in the young term and premature infant. The presence of serum albumin and α_1 -antitrypsin in feces may arise from either ingested milk or leakage from serum. Crossed immunoelectrophoresis of fecal extracts against antiwhey protein and antiserum protein antibodies showed reactivity with both of these proteins. Other soluble fecal proteins may include minor whey proteins, other serum proteins, or proteins arising from the infant's gut or intestinal flora. In the premature infant, leakage of such proteins into the gut may play a larger role than in the term infant due to his or her immature gut development.

Although the levels of intake of serum albumin, lactoferrin, and lysozyme were higher in the PTM-fed group, total excretion (milligrams per kilogram per day) of the proteins was very similar between the groups, which seems to reflect steady-state excretion. In contrast, mean levels of sIgA excretion (milligrams per kilogram per day) were 3.0-fold higher in the PTM-fed group than the PTM + F group, which may reflect the 3.3-fold higher intake of sIgA. Therefore, for sIgA the level of excretion may be mediated by intake, although this study and previous studies have failed to positively correlate intake and excretion.²⁰

Although metabolic balance studies tend to be biased toward overestimation of intake and underestimation of intake, when carried out carefully these errors can be limited. In addition, since the comparisons in this study were made between groups, error would be in the same direction. Therefore, in spite of their limitations, nitrogen balance studies provide a noninvasive, nonisotopic method for assessing nitrogen utilization from different diets.

In this study it was demonstrated that premature infants maintained on their own mother's milk attain nitrogen balance with nitrogen accretion rates similar to those of the reference fetus growing at the 50th percentile for the first 5 weeks postnatally. If we assume

that all of the fecal whey proteins are arising from persistence of milk proteins through the gastrointestinal tract, this represents a loss of up to 33% (PTM-fed) to 59% (PTM + F-fed) of the ingested protein and thus amino acids for protein synthesis. However, it must be cautioned that, as with NPN, without the use of labeled milk protein it is impossible to distinguish between fecal proteins that are of milk origin from those endogenously produced; therefore, these percentages may represent an overestimation. Although it was not studied in these infants, studies with other premature infants in the neonatal unit of Chedoke-McMaster Hospital showed that approximately 25% of ^{15}N -urea supplemented to human milk is retained by the infant.⁴² This level of retention may represent up to 5% of the infant's nitrogen needs. The potential loss of whey proteins via fecal excretion and the speculation that at least part of the NPN can be utilized by the infant for protein synthesis underscores the difficulty in determining what represents the "true" utilizable protein or nitrogen content of human milk.

This research was supported in part by a grant from the Medical Research Council of Canada.

We would like to thank Debra Fraser, BSc, and Ruthann Stanhope, RN, for their excellent technical assistance, and Barbara Brandon for her help in preparation of the manuscript. The cooperation of the nurses of the Neonatal Unit of Chedoke-McMaster Hospital and the parents whose infants were studied is greatly appreciated. Stephanie Atkinson, PhD, is a Career Scientist of the Ministry of Health of Ontario.

Cardiac Malformations in Relatives of Infants With Hypoplastic Left-Heart Syndrome

Joel I. Brenner, MD; Kate A. Berg, PhD; Daniel S. Schneider, MD; Edward B. Clark, MD; Joann A. Boughman, PhD

• In a pilot study of relatives of infants with hypoplastic left-heart syndrome (HLHS), we obtained a medical history, cardiovascular examination, and echocardiogram in 48 first-degree relatives of 11 probands with isolated HLHS and 3 with HLHS and noncardiac malformations. Echocardiography confirmed heart defects in 5 of 41 relatives of patients with isolated HLHS. In four instances, the cardiac abnormality was unrecognized. Among 7 relatives of infants with HLHS and extracardiac anomalies, no heart defects were detected. Cardiac defects occurred in first-degree relatives of probands at a frequency higher than previously predicted by an additive multifactorial model of inheritance. These findings suggest that first-degree relatives of HLHS probands may have an increased risk for subclinical cardiac defects and that genetic factors likely contribute to the cause of left-heart blood-flow lesions.

(AJDC. 1989;143:1492-1494)

Although hypoplastic left-heart syndrome (HLHS) accounts for only a small proportion of clinically recognized congenital cardiovascular malformations,^{1,2} it remains one of the most severe types of malformation, with an untreated mortality of 100% and an uncertain surgical future.^{3,4} Determining the cause of HLHS is important because of the major medical-surgical, psychological, and economic issues created by caring for the family faced with a newborn with HLHS. Recurrence-

risk counseling has been based on the assumption that HLHS has a multifactorial origin. Thus, a recurrence risk of 3%, the square root of the population frequency as predicted by the multifactorial model,⁵ has often been cited in the past.⁶

Recent data from a population-based study of congenital cardiovascular malformations in liveborn infants challenged this interpretation.⁷ We found that the recurrence risk, ie, the risk of a heart defect to relatives born before the study infant, was higher than predicted by the multifactorial model. For isolated HLHS, eg, the reported recurrence risk approached 13%. A similar pattern of increased recurrence risk had also been noted in recent clinical studies of parents with left-heart defects, where 12% to 26% of infants born to mothers or fathers with aortic stenosis were found to have congenital cardiovascular malformations, usually of a similar type.^{8,9} Concordance data from these studies, from a population referred for fetal echocardiography because of a prior infant with left-heart disease,¹⁰ and from experimental models reviewed by Clark,¹¹ suggest that left ventricular outflow tract defects, ranging from bicuspid aortic valve (BAV) to HLHS, may be developmentally related. Left-heart defects reported in affected relatives of infant patients led us to initiate a pilot study to document the existence and nature of congenital cardiovascular malformations and to investigate the possibility that the incidence of previously unrecognized structural cardiac defects might be higher than predicted by the multifactorial model in the relatives of infants with HLHS.

PATIENTS AND METHODS

Families for this pilot project were drawn from the Baltimore-Washington Infant Study, a population-based case-control study of congenital cardiovascular malforma-

tions in the State of Maryland, the District of Columbia, and five counties in Northern Virginia.¹ For our purposes, the diagnostic group with HLHS included only infants with aortic atresia and mitral stenosis-atresia with hypoplasia of the left ventricle. Diagnosis was confirmed by echocardiography, angiography, surgery, autopsy, or a combination of these.

Fourteen families in the Baltimore-Washington Infant Study who had at least one infant affected with HLHS registered with Pediatric Cardiology at the University of Maryland Medical System or The Johns Hopkins Hospital, Baltimore, Md, agreed to participate. First-degree family members were examined by one of us, a senior cardiologist (J.I.B. or E.B.C.). Blood pressure in the upper and lower extremities was taken manually, automatically, or by a combination of blood pressure devices with use of the appropriate cuff for age and size of the subject. Clinical cardiopulmonary examination was performed with special attention to the presence of pathologic murmurs, systolic clicks, and aortic-arch obstruction.

Echocardiography was performed under the direct supervision of a study center physician with the assistance of a skilled pediatric echocardiography technician. Standard M-mode measurements of left ventricular diastolic and systolic dimension; mitral valve excursion, and aortic and left atrial size were obtained. Real-time echocardiographic evaluation included detailed study of mitral valve motion and papillary muscle orientation. Real-time guided Doppler determination of mitral valve inflow and left ventricular outflow was also performed.

All echocardiographic tapes were evaluated by a second cardiologist who had not seen the family and was unaware of the physical examination results. The diagnosis of a heart defect was confirmed only when both cardiologists agreed on the presence of the defect as demonstrated by echocardiography and supported by physical examination. At the time of examination, a medical history and detailed pedigree were obtained from the parents.

This protocol was approved by the Human Subjects Review Committee at each institution. Each family provided informed consent before participation.

Accepted for publication July 10, 1989.

RESULTS

Of 33 local families with an infant diagnosed with HLHS, 14 were available and agreed to participate in the study. Of the remaining families, 2 families had moved out of state, 2 identified through searches of autopsy records were unwilling to become involved, and the other families declined the clinical testing procedures. No discernible differences were noted in patient diagnosis, family size, or demographics between participating and nonparticipating families.

Forty-eight first-degree relatives from 14 families were available for examination. Three fathers did not participate in the studies, and thus their cardiac status is unknown. In addition, one 14-month-old sibling had normal cardiopulmonary examination results but was too uncooperative for detailed echocardiographic evaluation.

All 14 infant patients were dead when their families were examined. Three of these infants had additional extracardiac anomalies, as shown in the Table. These 3 included 2 females with renal defects, 1 of whom had, in addition, a skeletal abnormality that was thought to be an autosomal dominant form of ectrodactyly, based on the family history (parent and second-degree relative). Cytogenetic analysis was not performed on either of these infants. The male infant was born with optic-nerve hypoplasia and a unilateral cataract of unknown cause. Autopsy findings were noncontributory, and he had a normal karyotype. No heart disease was noted in any first-degree relative.

Eleven infants had no recognized phenotypic abnormalities apart from their HLHS. In this group, echocardiographically normal relatives were found in 7 of the families. Among the 4 families in which abnormal echocardiographic findings were identified (Fig 1), none of the parents had reported or suspected that they had a heart defect when ini-

tially interviewed for the Baltimore-Washington Infant Study.

By clinical and echocardiographic examination, four parents were found to have a BAV. In 2 families, a single parent with BAV was noted, while in 1 family, both parents had BAV. One sibling with BAV and mild aortic stenosis had been identified before his sister was born with HLHS. The excessive pregnancy loss in this family was attributed to an incompetent cervix. Thus, among the families with isolated cases of HLHS, 5 (12.2%) of 41 of the examined relatives had a cardiac abnormality suspected by physical examination and confirmed by echocardiography; all defects involved the left ventricular outflow tract.

COMMENT

Aggregation of left-heart defects became evident to us from data analyzed in the Baltimore-Washington Infant Study.⁷ When isolated anatomic heart defects were grouped by presumed developmental mechanism, such as altered blood flow through the embryonic heart, the contrast was striking between the frequency of affected relatives—particularly siblings—of probands with left-heart defects compared with the relatives of probands with all other types of cardiac malformations (Fig 2). Moreover, there was a high degree of concordance of reported lesions in families. Evidence that a spectrum of left-heart defects may result from a single mechanism is also suggested by analysis of human heart specimens and the hearts of experimental animals.^{11,12} The phenotypic expression may range from mild defects, such as BAV, to the most clinically severe manifestation, HLHS.

Isolated congenital cardiovascular malformations have traditionally been thought to be multifactorial disorders, resulting from the small additive effects of several genes and from environmen-

Fig 1.—Pedigree of four families of proband (arrow) with hypoplastic left-heart syndrome and additional affected family members. Large solid symbols indicate patients with hypoplastic left-heart syndrome; partially shaded symbols, individuals with bicuspid aortic valve; small solid circles, abortuses; squares, males; circles, females; and slashes, dead.

tal factors.⁶ Recurrence risk is, therefore, usually lower than in mendelian disorders, and recurrence is modified for each family by the number of affected relatives and the severity of defect in the proband. In the report from the Baltimore-Washington Infant Study, the multifactorial expectation of recurrence of 1% to 5% was observed in mothers and fathers of infants with left-heart defects, and in mothers, fathers, and siblings of infants with all other types of congenital cardiovascular malformations. However, among sibling probands with left-heart defects, the reported frequency substantially exceeded the frequency expected under a multifactorial mode. Moreover, the affected relatives of infants with left-heart defects, though concordant with the developmental group, were not always concordant for a specific anatomic lesion. These findings led us to investigate a subset of available families in more detail.

Twelve percent of the examined relatives of a subset of infants with isolated HLHS had BAV, compared with a population estimate for BAV of 0.9% to 1.3%.¹³ Bicuspid aortic valve may be considered a subclinical left-heart blood-flow defect. This suggests that minor left-heart defects, compatible with essentially normal life and of undetected, may occur more frequently among relatives of infants with HLHS than in the general population.

Several possible explanations may account, at least in part, for the finding of higher rates of left-heart lesions in

Fig 2.—Percentages of cardiac malformations among first-degree relatives of infants with congenital heart disease, from the Baltimore-Washington Infant Study.⁷

study families. First, the increase over population frequency may be a chance occurrence in this preliminary study. Second, mild forms of the spectrum of left-heart malformations in families of infants with HLHS may reflect risks appropriate to a multifactorial threshold trait with identification through severely affected probands, thus accounting for the high frequency of affected relatives. According to the Carter hypothesis,¹⁴ severely affected probands would have higher frequencies of affected first-degree relatives than more mildly affected patients. More data from relatives of patients representing the spectrum of left outflow defects would be necessary to confirm this hypothesis.

A third alternative is that, in at least some of the families, left-heart defects may be under the control of a major gene or genes with variable expression and identification limited by selection against infants with HLHS, since these individuals do not reproduce. Under this hypothesis, families in which the gene(s) was segregating would have higher proportions (up to 50% if single-gene dominant) of individuals with the "affected" genotype. Expression of that genotype could then depend on addi-

tional genetic or environmental modifiers, so that some individuals with the genetic predisposition could have milder expression, ie, BAV. All genotypes surviving the newborn period, by definition, would have milder lesions than HLHS.

This pilot study cannot prove any of these hypotheses, especially with the potential for heterogeneity. Formal genetic-model testing requires larger sample sizes, and further studies are necessary to calculate accurate risks for genetic counseling to be established.

In the short term, clinical management can be altered by offering fetal echocardiography to evaluate subsequent pregnancies in families in which serious left-heart defects have occurred. Echocardiography of first-degree relatives of infants with HLHS and other severe left-heart malformations can also be considered in these families to identify the presence of subclinical defects such as BAV, which would modify recurrence counseling even if the multifactorial model were used. The use of antibiotic prophylaxis and periodic monitoring by a cardiologist should also be considered.

In an era when surgical palliation of HLHS or cardiac transplantation is be-

ginning to hold promise for infants, allowing growth and maturation, it becomes even more urgent to investigate potential genetic influences in congenital cardiovascular malformations. When continued improvement in surgical technique and medical control of rejection allow survival of infants with HLHS into their reproductive years, the full influence of the severe end of the spectrum of left-heart flow lesions will be realized.

This study was supported in part by a grant from the American Heart Association, Maryland Affiliate, Baltimore, and the Alpha Phi Foundation, Evanston, Ill.

Charlotte Ferencz, MD, and the staff of the Baltimore-Washington Infant Study group allowed use of the study resources, and Catherine A. Neill, MD, provided counsel on the project. Pat Boland, LCSW, and the echocardiography technologists, Joyce Cordier, RDMS, Kathy Baker, RDMS, and Cathy Hensley, assisted with this project.

SUBJECT INDEX TO VOLUME 143

The following index is an alphabetical list of significant subjects presented in this volume. Books reviewed are listed alphabetically by first author under the heading "BOOK REVIEWS." The month is given as a two letter notation in parentheses. Archive articles are indexed by subject and under the heading AJDC ARCHIVES; original year of publication appears in parenthesis before the author's name.

- A**
- Abdomen**
Umbilical cord circumference at birth (letter) [Patel] 633 (Je)
- Abdominal Cramps see Colic**
- Abnormalities**
Anomalous origin of right pulmonary artery from aorta: "hemitruncus" [Gumbiner] 1209 (Oc)
Circumcision and urinary tract abnormalities (letters) [Rockney, Hopp] (reply) [Herzog] 1261, 1262 (No)
Congenital cardiovascular malformations in twins and triplets from population-based study [Berg] 1461 (De)
Congenital laryngeal atresia [Fang] 625 (My)
Congenital rhabdomyomatous mesenchymal hamartoma of skin [Levkoff] 963 (Au)
Correction of atrioventricular septal defect [Vet] 1361 (No)
Ectrodactyly, ectodermal dysplasia, and clefting associated with thymic aplasia (letter) [Jhaveri] 12 (Ja)
Fetal surgery in 1990s [Evans] 1431 (De)
Hormonal therapy for cryptorchidism with combination of human chorionic gonadotropin and follicle-stimulating hormone: success and relapse rate [Saggese] 980 (Au)
Intrathoracic stomach with volvulus [Bonadio] 503 (Ap)
Mucopolysaccharidosis I presenting with endocardial fibroelastosis of infancy [Stephan] 782 (Jy)
Neonatal intensive care: at what price? [Bedrick] 451 (Ap)
Neurological and developmental findings in children with cataracts [Pike] 706 (Je)
Origins of cerebral palsy [Naeye] 1154 (Oc)
Perinatal abnormalities and subhypothalamic bright spot on magnetic resonance imaging in pituitary dwarfs (letter) [Okabe] 1394 (De)
Perinatal asphyxia and cerebral palsy: fact, fiction, or legal prediction? [Bedrick] 1139 (Oc)
Perinatal outcome of infants exposed to cocaine and/or heroin in utero [Fulroth] 905 (Au)
Single umbilical artery: report of 159 cases [Leung] 108 (Ja)
State-of-the-art reconstructive surgery for bladder exstrophy at Johns Hopkins Hospital [Gearhart] 1475 (De)
TEARS: does domestic violence play role? (letter) [Rimsza] 137 (Fe)
Vaginal opening measurement in prepubertal girls [Goff] 1366 (No)
- Abnormalities, Drug-Induced**
Aminoglycoside ototoxicity in cystic fibrosis: evaluation by high-frequency audiometry [McRorie] 1328 (No)
Ebstein's anomaly and extracardiac defects [Siebert] 570 (My)
- Abnormalities, Multiple**
Acute systemic organ injury in term infants after asphyxia [Periman] 617 (My)
Ebstein's anomaly and extracardiac defects [Siebert] 570 (My)
Lack of associated renal anomalies in familial polythelia (letter) [Bortz] 883 (Au)
Neurological and developmental findings in children with cataracts [Pike] 706 (Je)
Right-upper-lobe esophageal bronchus (with VATER anomalies) [Davies] 251 (Fe)
- Abortion**
Fetal tissue transplantation [Nadler] 149 (Fe)
- Abscess**
Esophageal obstruction and abscess formation secondary to impacted, eroding tiddlywink [Katz] 961 (Au)
Extrapleural effusion of retropharyngeal origin [Martinot] 1207 (Oc)
Nasal septal abscess; inflammatory nasal polyps; intranasal glioma [Wiatrak] 501 (Ap)
Pyomyositis in child with acquired immunodeficiency syndrome: patient report and brief review [Raphael] 779 (Jy)
- Absenteeism**
Determinants of school performance in children with chronic asthma [Gutstadt] 471 (Ap)
School breakfast program and school performance [Meyers] 1234 (Oc)
- Absorption**
Effect of pancreatic enzyme supplements on iron absorption [Zempsky] 969 (Au)
Manganese absorption from human milk, cow's milk, and infant formulas in humans [Davidsson] 823 (Jy)
- Absorption, Intestinal see Intestinal Absorption**
- Absorption, Skin see Skin Absorption**
- Accident Prevention**
Child passenger safety: past, present, and future [Christoffel] 1271 (No)
Choking on 'large' object: applications for regulation and practice (letter) [Meyers] 1182 (Oc)
Falls from pickup trucks during childhood (letter) [Tong] 997 (Se)
Household electrical injuries in children: epidemiology and identification of available hazards [Baker] 59 (Ja)
Injuries among 4- to 9-year old restrained motor vehicle occupants by seat location and crash impact site [Agran] 1317 (No)
Injury prevention: drowning (letter) [Smith] (reply) [Noyes] 272 (Mr)
Playground-related injuries in preschool-aged children—United States, 1983-1987, leads from *MMWR*, 125 (Ja)
Queens Boulevard Pedestrian Safety Project—New York City, leads from *MMWR*, 525 (My)
Recurrent injuries in schoolchildren [Boyce] 338 (Mr)
Strategies to prevent household electrical injuries in children (letter) [Bond] 1130 (Oc)
- Accident Proneness**
Recurrent injuries in schoolchildren [Boyce] 338 (Mr)
Unintentional injuries: risk factors in preschool children [Bourguet] 556 (My)
- Accidental Falls see Accidents**
- Accidents**
Falls from pickup trucks during childhood (letter) [Tong] 997 (Se)
Safety hazard with intravenous pumps (letter) [Schwartz] 1390 (De)
Unintentional injuries: risk factors in preschool children [Bourguet] 556 (My)
Unintentional poisoning mortality—United States, 1980-1986, leads from *MMWR*, 645 (Je)
- Accidents, Home**
Household electrical injuries in children: epidemiology and identification of available hazards [Baker] 59 (Ja)
Strategies to prevent household electrical injuries in children (letter) [Bond] 1130 (Oc)
Survey of severe eye injuries in children [DeRespinis] 711 (Je)
Unintentional injuries: risk factors in preschool children [Bourguet] 556 (My)
- Accidents, Traffic**
Child passenger safety: past, present, and future [Christoffel] 1271 (No)
Injuries among 4- to 9-year old restrained motor vehicle occupants by seat location and crash impact site [Agran] 1317 (No)
Queens Boulevard Pedestrian Safety Project—New York City, leads from *MMWR*, 525 (My)
- Acculturation**
Breast-feeding pattern among Indochinese immigrants in northern California [Romero-Gwynn] 804 (Jy)
- Achievement**
Determinants of school performance in children with chronic asthma [Gutstadt] 471 (Ap)
School breakfast program and school performance [Meyers] 1234 (Oc)
Theophylline and school performance (letter) [Du Hamel] (reply) [Strunk] 1258 (No)
- Acid-Base Imbalance**
Pneumomediastinum and subcutaneous emphysema caused by diabetic hyperpnea [Bullaboy] 93 (Ja)
- Acidosis, Diabetic**
Hyperglycemic acidosis with mortality in Kearns-Sayre syndrome (letter) [Welch] 1135 (Oc)
- Acidosis, Lactic**
Fructose-1,6-diphosphatase deficiency: 20-year follow-up (letter) [Elpeleg] 140 (Fe); correction 1345 (No)
- Acids**
Protein intake and renal function in children [Kano] 160 (Fe)
- Acquired Immunodeficiency Syndrome**
Acquired immunodeficiency syndrome among adolescents: case surveillance profiles in New York City and rest of United States [Vermund] 11 (Oc)
Adolescents' knowledge and beliefs about AII did government brochure help? (letter) [Zim] 518 (My)
Elevated serum levels of tumor necrosis factor associated with progressive encephalopathy children with acquired immunodeficiency syndrome [Mintz] 771 (Jy)
First 100,000 cases of acquired immunodeficiency syndrome—United States, leads from *MMWR* 1274 (No)
HIV-related beliefs, knowledge, and behavior among high school students, leads from *MMWR* 145 (Fe)
International adoption: introduction for physicians [Hostetter] 325 (Mr)
Pregnant adolescent prostitute [Deisher] 1162 (C)
Prognostic factors and life expectancy in child with acquired immunodeficiency syndrome and *Pneumocystis carinii* pneumonia [Bernstein] 775 (Jy)
Pyomyositis in child with acquired immunodeficiency syndrome: patient report and brief review [Raphael] 779 (Jy)
Secondary disorders of complement system [Jchenfeld] 595 (My)
Toxoplasmosis needs evaluation: overview and proposals [Koskineniemi] 724 (Je)
- Acrodermatitis**
Mucocutaneous lymph node syndrome: is there a relationship to mercury exposure? (letter) [Aschner] 1133, (reply) [Krowchuk] 1134 (Oc)
- Acyclovir**
Antiviral drugs in pediatrics [Balfour] 1307 (No)
- Acyl Coenzyme A**
Relative carnitine insufficiency in children with type I diabetes mellitus [Winter] 1337 (No)
- Adamantane**
Antiviral drugs in pediatrics [Balfour] 1307 (No)
- Adenoids**
Acute suppurative adenoiditis (letter) [Weir] 998 (C)
- Adhesives**
Adhesive tape remover pads: risk to newborn? (letter) [Lacouture] 1391 (De)
- Administration Schedule, Drug see Drug Administration Schedule**
- Administration, Topical**
Tack up warning on TAC (letter) [Mofenson] 1 (My)
- Adolescence**
Adolescent health: synopsis of conference [Brow] 466 (Ap)
Adolescents' knowledge and beliefs about AII did government brochure help? (letter) [Zim] 518 (My)
Age, gender, and metabolic control in children and adolescents with diabetes (letter) [Zimet] 11 (Oc)
Child passenger safety: past, present, and future [Christoffel] 1271 (No)
Chlamydia and adolescent girl: enzyme immunoassay as screening tool [Soren] 51 (Ja)
Connectedness [McAnarney] 453 (Ap)
High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)
HIV-related beliefs, knowledge, and behavior among high school students, leads from *MMWR* 145 (Fe)
Interactions of alcohol and nutrition (letter) [Cunha Ferreira] 519 (My); correction, 1110 (Se)
Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)
Long-term outcome of adolescents with anorexia nervosa [Kreipe] 1322 (No)
Predicting maximum oxygen uptake in adolescents

[Hergenroeder] 673 (Je)
 Prolactinoma in adolescent girl: unusual response to bromocriptine therapy (letter) [Tiwayi] 521 (My)
 Psychosocial determinants of compliance in adolescents with iron deficiency [Cromer] 55 (Ja)
 Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)
Adolescent Behavior
 Acquired immunodeficiency syndrome among adolescents: case surveillance profiles in New York City and rest of United States [Vermund] 1220 (Oc)
 Adolescence: what is normal? [Offer] 731 (Je)
 Adolescent contraceptive use and parental notification [Demetriou] 1166 (Oc)
 Adolescent health: synopsis of conference [Brown] 466 (Ap)
 Adolescent heterosexual relationship and its association with sexual and contraceptive behavior of black girls [DuRant] 1467 (De)
 Adolescents and condoms: associations of beliefs with intentions to use [Kegeles] 911 (Au)
 Clinical predictors of *Chlamydia trachomatis* endocervicitis in adolescent women: looking for right combination [Remafedi] 1437 (De)
 Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)
 Firearm ownership among nonurban adolescents [Sadowski] 1410 (De)
 High prevalence rate of human papillomavirus infection and association with positive Papanicolaou smears in sexually active adolescents [Rosenfeld] 1443 (De)
 HIV-related beliefs, knowledge, and behaviors among high school students, leads from *MMWR*, 145 (Fe)
 Reported sexual behaviors and self-esteem among young adolescents [Orr] 86 (Ja)
 Short-term memory impairment in cannabis-dependent adolescents [Schwartz] 1214 (Oc)
 What causes sexual assault? (letter) [Margolis] (reply) [Jenny] 137 (Fe)
Adolescent Medicine
 Adolescent health: synopsis of conference [Brown] 466 (Ap)
 Sexually transmitted diseases curriculum in adolescent medicine [Johnson] 1073 (Se)
Adolescent Pregnancy see Pregnancy in Adolescence
Adolescent Psychology
 Adolescence: what is normal? [Offer] 731 (Je)
 Adolescent heterosexual relationship and its association with sexual and contraceptive behavior of black girls [DuRant] 1467 (De)
 Adolescents and condoms: associations of beliefs with intentions to use [Kegeles] 911 (Au)
 Reported sexual behaviors and self-esteem among young adolescents [Orr] 86 (Ja)
Adoption
 International adoption: introduction for physicians [Hostetter] 325 (Mr)
Adrenal Cortex Hormones
 Bone mineral status in hypopituitarism (letter) [Arisaka] 272 (Mr)
 Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)
 Corticosteroids as adjunctive therapy in bacterial meningitis: meta-analysis of clinical trials [Havens] 1051 (Se)
 Does methylprednisolone pulse therapy deteriorate course of rapidly progressive IgA nephropathy? (letter) [Itami] 441, (reply) [Weich] 442 (Ap)
 Magnetic resonance imaging and dexamethasone therapy for bacterial meningitis [Lebel] 301 (Mr)
 Treatment of croup: critical review [Skolnik] 1045 (Se)
Adrenaline see Epinephrine
Adrenocorticotrophic Hormone
 Low-dose alternate-day corticotropin therapy in treatment of childhood seizures (letter) [Dooley] 1263 (No)
Affect
 Evaluation of camp program for siblings of children with cancer [Sahler] 690 (Je)
Agammaglobulinemia
 Secondary disorders of complement system [Eichenfeld] 595 (My)
Age Factors
 Age, gender, and metabolic control in children and adolescents with diabetes (letter) [Zimet] 1134 (Oc)
 Age-related patterns of violent death, Cook County, Illinois, 1977 through 1982 [Christoffel] 1403 (De)

Bone mineral content in black and white children 1 to 6 years of age: early appearance of race and sex differences [Li] 1346 (No)
 Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)
 Effect of respiratory viral infections on patients with cystic fibrosis [Ramsey] 662 (Je)
Haemophilus B polysaccharide vaccine: antibody kinetics in 17- to 71-month-old children [Ramsey] 28 (Ja)
 Immunization after invasive *Haemophilus influenzae* type b disease: serologic response to conjugate vaccine [Edwards] 31 (Ja)
 Non-group A streptococci in pharynx: pathogens or innocent bystanders? [Hayden] 794 (Jy)
 Recurrent injuries in schoolchildren [Boyce] 338 (Mr)
 Risk factors for infant botulism in United States [Spika] 828 (Jy)
 Serum alkaline phosphatase and serum zinc concentrations in preterm infants with rickets and fractures [Koo] 1342 (No)
 Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)
 Vaginal opening measurement in prepubertal girls [Goff] 1366 (No)
Aged
 Adult immunization: knowledge, attitudes, and practices—DeKalb and Fulton Counties, Georgia, 1988, leads from *MMWR*, 281 (Mr)
Agranulocytosis
Klebsiella pneumoniae bacteremia in children: 57 cases in 10 years [Bonadio] 1061 (Se)
 Risk of infectious complications in well-appearing children with transient neutropenia [Alario] 973 (Au)
AIDS-Related Complex
 First 100,000 cases of acquired immunodeficiency syndrome—United States, leads from *MMWR*, 1274 (No)
AIDS Serodiagnosis
 Elevated serum levels of tumor necrosis factor are associated with progressive encephalopathy in children with acquired immunodeficiency syndrome [Minz] 771 (Jy)
 Natural history and serologic diagnosis of infants born to human immunodeficiency virus-infected women [Johnson] 1147 (Oc)
Airway Obstruction
 Choking on 'large' object: applications for regulation and practice (letter) [Meyers] 1132 (Oc)
 Comparison of airway pathologic lesions after high-frequency jet or conventional ventilation [Polak] 228 (Fe)
 Congenital laryngeal atresia [Fang] 625 (My)
 Strategies to prevent household electrical injuries in children (letter) [Bond] 1130 (Oc)
 Treatment of croup: critical review [Skolnik] 1045 (Se)
AJDC ARCHIVES
 Pediatric biographies: George Armstrong (1930) [Ruhrah] 242; commentary [Fulginiti] 244 (Fe)
Albuterol
 Experience with metered-dose inhaler with spacer in pediatric emergency department [Benton] 678 (Je)
Alcohol Drinking
 Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)
Alcoholism
 Interactions of alcohol and nutrition (letter) [da Cunha Ferreira] 519 (My); correction, 1110 (Se)
Alkaline Phosphatase
 Hypophosphatemia in breast-fed low-birth-weight infants following initial hospital discharge [Hall] 1191 (Oc)
 Marked transient alkaline phosphatemia following pediatric liver transplantation [Koneru] 669 (Je)
 Serum alkaline phosphatase and serum zinc concentrations in preterm infants with rickets and fractures [Koo] 1342 (No)
 Simultaneous transient hyperphosphatemia in set of twins (letter) [Kraut] 881 (Au)
Allergens
 Gastrointestinal milk intolerance of infancy [Berezin] 361 (Mr)
Allergy and Immunology
 Use of adrenergic bronchodilators by pediatric allergists and pulmonologists [Newcomb] 481 (Ap)
Alopecia Area
 Small, single-vertex lesion of scalp aplasia cutis congenita; *Trichophyton tonsurans*; aplasia cutis congenita [Cohen] 621 (My)
Alprostadil
 Prostaglandin E₁ selectively reduces group B beta-hemolytic streptococci-induced pulmonary hyper-

tension in newborn piglets [Hammerman] 343 (Mr)
Altitude
 Neonatal hyperbilirubinemia at high altitude [Leibson] 983 (Au)
Amantadine
 Antiviral drugs in pediatrics [Balfour] 1307 (No)
Ambulatory Care
 Does residents' continuity clinic provide primary care? [Wilson] 809 (Jy)
 Impact of fever health education on clinic utilization [Robinson] 698 (Je)
 Informed consent for lumbar puncture [Botkin] 899 (Au)
 Management of diabetes in pediatric resident continuity clinics [Kronz] 1173 (Oc)
 Prescription of psychotropics to children in office-based practice [Kelleher] 855 (Jy)
Ambulatory Pediatric Association
 29th annual meeting, May 1-5, 1989, Washington, D.C., program, 397-411; abstracts, 412-438 (Ap)
Amenorrhea
 Gonorrheal vulvovaginitis; labial fusion; imperforate hymen [Rimsza] 381 (Mr)
American Academy of Pediatrics
 Circumcision and urinary tract abnormalities (letters) [Rockney, Hoppl] (reply) [Herzog] 1261, 1262 (No)
 Smoking policy in pediatric hospitals and wards [Jenista] 567 (My)
 Twice-daily therapy for strep? (letter) [Gill] (reply) [Gerber] 997 (Se)
American College of Obstetricians and Gynecologists
 Education about adult domestic violence in U.S. And Canadian medical schools, 1987-88, leads from *MMWR*, 447 (Ap)
American Heart Association
 Twice-daily therapy for strep? (letter) [Gill] (reply) [Gerber] 997 (Se)
AMERICAN JOURNAL OF DISEASES OF CHILDREN
 List of reviewers for *AJDC* 1988, 21 (Ja)
American Medical Association
 Congress on Adolescent Health, May 12-14, 1988, 466 (Ap)
American Pediatric Society
 1989 annual meeting, May 1-4, 1989, Washington, D.C., program, 410-411; abstracts 429-438 (Ap)
 Tribute to American Pediatric Society on its 100th anniversary [Andrews] 180 (Fe)
American Samoa see Western Samoa
Ammonia
 On combination therapy with benzoate and piridoxilate (letter) [Cyr] 1392 (De)
Amnion
 TEARS: does domestic violence play role? (letter) [Rimsza] 137 (Fe)
Amoxicillin
Campylobacter pylori gastritis and peptic ulcer in children (letters) [Oderda, Chiesa] 877, (reply) [Dahms] 878 (Au)
 Comparison of amoxicillin and clavulanic acid (Augmentin) for treatment of nonbullous impetigo [Dagan] 916 (Au)
 Prophylaxis of recurrent acute otitis media and middle-ear effusion: comparison of amoxicillin with sulfamethoxazole and trimethoprim [Principi] 1414 (De)
Amphetamines
 High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)
Ampicillin
Campylobacter pylori gastritis and peptic ulcer in children (letters) [Oderda, Chiesa] 877, (reply) [Dahms] 878 (Au)
Ampicillin Resistance
 Emergence of isolates resistant to ampicillin [Rupar] 1033 (Se)
Anabolic Steroids
 High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)
Analgesics, Anti-Inflammatory
 Pediatricians' recommendations for antipyretic agents with DTP immunizations: survey of current practice (letter) [Flanagan] 517 (My)
Anaphylaxis
 Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)
Anemia
 Septic arthritis in children with hemophilia [Pappo] 1226 (Oc)
Anemia, Hypochromic
 Effect of pancreatic enzyme supplements on iron absorption [Zempsky] 969 (Au)
Anemia, Neonatal
 Anti-*Staphylococcus aureus* IgE antibodies for diagnosis of hyperimmunoglobulinemia E-recur-

rent infection syndrome in infancy [Lavoie] 1038 (Se)

Anemia, Sickle Cell
Cholecystectomy in sickle cell anemia (letter) [Gerry] 764 (Jy)

Infections and sickle cell disease in eastern Saudi Arabian children [Mouzan] 205 (Fe)

Secondary disorders of complement system [Eichenfield] 595 (My)

Anesthetics, Local
Tack up warning on TAC (letter) [Mofenson] 519 (My)

Anorexia Nervosa
Long-term outcome of adolescents with anorexia nervosa [Kreipe] 1322 (No)

Low serum complement levels in anorexia nervosa (letter) [Sigal] 1391, (reply) [Eichenfield] 1392 (De)

Secondary disorders of complement system [Eichenfield] 595 (My)

Anoxemia
Gastroesophageal reflux-induced hypoxemia in infants with apparent life-threatening event(s) [See] 951 (Au)

Hematologic syndrome of growth-retarded infants (letter) [Meberg] (reply) [Philip] 1260 (No)

High-frequency jet ventilation in neonatal pulmonary hypertension [Carlo] 233 (Fe)

Home oxygen therapy for chronic lung disease in extremely low-birth-weight infants [Hudak] 357 (Mr)

Increased nucleated red blood cell counts in small for gestational age infants with very low birth weight [Philip] 164 (Fe)

Anoxia
Symmetrical thalamic degeneration with calcifications of infancy [DiMario] 1056 (Se)

Anthropometry
Hypophosphatemia in nutritional recovery syndrome [Mezoff] 1111 (Se)

Antibiotic Resistance see Drug Resistance, Microbial

Antibiotics
Neonatal *Staphylococcus epidermidis* meningitis with unremarkable CSF examination results [Gruskay] 580 (My)

Reconsideration of IgM-enriched intravenous immunoglobulin for neonatal sepsis (letter) [Hall] (reply) [Haque] 766 (Jy)

Use of intravenous immunoglobulin in treatment of neonatal sepsis (letter) [Kim] 1257 (No)

Antibiotics, Aminoglycoside
Aminoglycoside ototoxicity in cystic fibrosis: evaluation by high-frequency audiometry [McRorie] 1328 (No)

Predictors of trough serum gentamicin concentrations in neonates [Keyes] 1419 (De)

Antibiotics, Beta-Lactam see Antibiotics, Lactam

Antibiotics, Lactam
Acute suppurative adenoiditis (letter) [Weir] 998 (Se)

Antibodies, Bacterial
Haemophilus B polysaccharide vaccine: antibody kinetics in 17-to 71-month-old children [Ramsey] 28 (Ja)

Immunization after invasive *Haemophilus influenzae* type b disease: serologic response to conjugate vaccine [Edwards] 31 (Ja)

Antibody Formation
Efficacy and immunogenicity of acellular pertussis vaccine by manufacturer and patient age [Aoyama] 655 (Je)

Antigen-Antibody Complex
Kawasaki disease with thrombocytosis followed by thrombocytopenia purpura in same patient (letter) [Lipnick] 139 (Fe)

Antigen-Antibody Reactions
Haemophilus B polysaccharide vaccine: antibody kinetics in 17-to 71-month-old children [Ramsey] 28 (Ja)

Immunization after invasive *Haemophilus influenzae* type b disease: serologic response to conjugate vaccine [Edwards] 31 (Ja)

Anti-Infective Agents, Local
Epidemic methicillin-gentamicin-resistant *Staphylococcus aureus* in neonatal intensive care unit [Reboli] 34 (Ja)

Antipyretics see Analgesics, Anti-Inflammatory

Antiseptics see Anti-Infective Agents, Local

Antitoxins
Recommendations of Immunization Practices Advisory Committee (ACIP): general recommendations on immunization, leads from *MMWR*, 1013 (Se)

Antiviral Agents
Antiviral drugs in pediatrics [Balfour] 1307 (No)

Anus, Imperforate
Right-upper-lobe esophageal bronchus (with

VATER anomalies) [Davies] 251 (Fe)

Anxiety
Educational booklet diminishes anxiety in parents whose children receive total parenteral nutrition [Laine] 374 (Mr)

Aorta
Anomalous origin of right pulmonary artery from aorta: "hemitruncus" [Gumbiner] 1209 (Oc)

Complex congenital heart disease after in vitro fertilization (letter) [Marino] 1136 (Oc)

Appar Score
Acute systemic organ injury in term infants after asphyxia [Perlman] 617 (My)

Origins of cerebral palsy [Naeye] 1154 (Oc)

Perinatal asphyxia and cerebral palsy: fact, fiction, or legal prediction? [Bedrick] 1139 (Oc)

Apnea
Cardiorespiratory patterns during alarms in infants using apnea/bradycardia monitors [Nathanson] 476 (Ap)

Gastroesophageal reflux-induced hypoxemia in infants with apparent life-threatening event(s) [See] 951 (Au)

Nasal intermittent positive-pressure ventilation offers no advantages over nasal continuous positive airway pressure in apnea of prematurity [Ryan] 1196 (Oc)

Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Czarnoff] 583 (My)

Appendicitis
Pylephlebitis secondary to unsuspected appendiceal rupture [Giuliano] 1099 (Se)

Appointments and Schedules
Computerized patient scheduling in outpatient residency practices [Quattlebaum] 1333 (No)

Arachnidism
Loxosceles reclusa; bite of brown recluse spider; typical bite of brown recluse spider with local cyanotic pustule and necrosis [Demmler] 843 (Jy)

Armstrong, George (1719-1787)
George Armstrong (1719-1787): founder of first dispensary for children [Bloch] 239 (Fe)

Pediatric biographies: George Armstrong (1930) [Ruhrah] 242; commentary [Fulginiti] 244 (Fe)

Arteriovenous Fistula
Pulmonary arteriovenous shunting in child with cirrhosis of liver [Crarry] 749 (Je)

Arthritis, Infectious
Septic arthritis in children with hemophilia [Pappo] 1226 (Oc)

Arthritis, Septic see Arthritis, Infectious

Asian Americans
Breast-feeding pattern among Indochinese immigrants in northern California [Romero-Gwynn] 804 (Jy)

Asphyxia Neonatorum
Acute systemic organ injury in term infants after asphyxia [Perlman] 617 (My)

Origins of cerebral palsy [Naeye] 1154 (Oc)

Perinatal abnormalities and subhypothalamic bright spot on magnetic resonance imaging in pituitary dwarfs (letter) [Okabe] 1394 (De)

Perinatal asphyxia and cerebral palsy: fact, fiction, or legal prediction? [Bedrick] 1139 (Oc)

Aspiration see Respiration

Aspiration Biopsy see Biopsy, Needle

Aspirin
Clinical trial of single-dose intravenous gamma globulin in acute Kawasaki disease: preliminary report [Engle] 1300 (No)

Hidden salicylates (letter) [Szap] 142 (Fe)

Assimilation see Acculturation

Asthma
Circumstances surrounding deaths of children due to asthma: case control study [Miller] 1294 (No)

Determinants of school performance in children with chronic asthma [Gutstadt] 471 (Ap)

Effects of theophylline on behavior and learning in children with asthma [Rappaport] 368 (Mr)

Efficacy and safety of home nebulizer therapy for children with asthma [Zimo] 203 (Fe)

Experience with metered-dose inhaler with spacer in pediatric emergency department [Benton] 678 (Je)

Pulmonary hypertension and asthma in 2 patients with congenital heart disease [Rothman] 977 (Au)

Theophylline and school performance (letter) [Du Hamel] (reply) [Strunk] 1258 (No)

Use of adrenergic bronchodilators by pediatric allergists and pulmonologists [Newcomb] 481 (Ap)

Athletic Injuries
Recurrent injuries in schoolchildren [Boyce] 338 (Mr)

Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)

Survey of severe eye injuries in children [DeRospinis] 711 (Je)

Attention Deficit Disorder with Hyperactivity
Comment on 'pediatrician as consultant' (lett [Levenson] 641, (reply) [Stickler] 642 (Je)

Methylphenidate in children with seizures and attention-deficit disorder [Feldman] 1081 (Se)

Parent, teacher, child: trilateral approach to attention deficit disorder [Cohen] 1229 (Oc)

Attitude
Evaluation of camp program for siblings of child with cancer [Sahler] 690 (Je)

Attitude of Health Personnel
Advising parents to stop smoking: opportunities and barriers in pediatric practice [Frankows] 1091 (Se)

Attitudes toward mental illness prevention in routine pediatric practice [Yager] 1089 (Se)

Attitude to Health
Psychosocial determinants of compliance in adolescents with iron deficiency [Cromer] 55 (Ja)

Audiometry
Aminoglycoside ototoxicity in cystic fibrosis: evaluation by high-frequency audiometry [McRorie] 1328 (No)

Auditory Threshold
Aminoglycoside ototoxicity in cystic fibrosis: evaluation by high-frequency audiometry [McRorie] 1328 (No)

Autoantibodies
Frequency of autoantibodies in normal children [Martini] 493 (Ap)

Autonomic Nervous System
Hirschsprung's disease and ocular autonomic neuromuscular function (letter) [O'Connor] 1137 (Oc)

Azidothymidine see Zidovudine

B

Bacteremia see Septicemia

Bacteria, Anaerobic
Breath hydrogen in preterm infants (letter) [Svenson] 1262 (No)

Morbidity and mortality in children with pyogenic liver abscess [Pineiro-Carrero] 1424 (De)

Bacterial Infections
Acute suppurative adenoiditis (letter) [Weir] 998 (Se)

Chronic sinusitis: disease of all ages [Rachelefsky] 886 (Au)

Clinical and bacteriologic features of chronic sinusitis in children [Tinkelman] 938 (Au)

Infections and sickle cell disease in eastern Saudi Arabian children [Mouzan] 205 (Fe)

Neonatal neutrophil host defense: prospects for immunologic enhancement during neonatal sepsis [Cairo] 40 (Ja)

Reconsideration of IgM-enriched intravenous immunoglobulin for neonatal sepsis (letter) [H. (reply) [Haque] 766 (Jy)

Use of intravenous immunoglobulin in treatment of neonatal sepsis (letter) [Kim] 1257 (No)

Bacterial Vaccines
Haemophilus B polysaccharide vaccine: antibody kinetics in 17-to 71-month-old children [Ramsey] 28 (Ja)

Immunization after invasive *Haemophilus influenzae* type b disease: serologic response to conjugate vaccine [Edwards] 31 (Ja)

Bacteriophage Typing
Epidemic methicillin-gentamicin-resistant *Staphylococcus aureus* in neonatal intensive care unit [Reboli] 34 (Ja)

Balloon Dilatation
Pediatric coin ingestions: prospective study of location and symptoms [Schunk] 546 (My)

Barium
Evaluation of vomiting infant [Foley] 660 (Je)

Bayes Theorem see Probability

Behavior, Adolescent see Adolescent Behavior

Beriberi
Beriberi in Southeast Asian adolescent (lett [Vrchota] 270 (Mr)

Beta-Lactam Antibiotics see Antibiotics, Lactam

Beta-Thalassemia see Thalassemia

Bezoars
Bubble gum bezoar [Truex] 253 (Fe)

Sunflower seed bezoar presenting as diarrhea (letter) [Dent] 643 (Je)

Bibliography
Physiotherapy for children with cerebral palsy: evidence for its efficacy [Tirosh] 552 (My)

Bicycling see Sports

Bile Acids and Salts
Vitamin K absorption capacity and its association with vitamin K deficiency [Shinzawa] 686 (Je)

Bilirubin
Capillary and venous bilirubin values: they are different—and how! (letter) [Eidelman] 642 (Je)

Neonatal hyperbilirubinemia at high altitude

- [Leibson] 983 (Au)

Pediatric biographies: George Armstrong (1930) [Ruhrah] 242; commentary [Fulginiti] 244 (Fe)

Pediatric marketplace [Martinez] 924 (Au)

Prescription of psychotropics to children in office-based practice [Kelleher] 855 (Jy)

Prospective reimbursement and pediatric services [Singleton] 292 (Mr)

Recommendations of Immunization Practices Advisory Committee (ACIP): general recommendations on immunization, leads from *MMWR*, 1013 (Se)

Updating immunization status at discharge (letter) 879 [Walterspiel] (Au)

Child, Hospitalized

Educational booklet diminishes anxiety in parents whose children receive total parenteral nutrition [Laine] 374 (Mr)

Pediatric patients, race, and DRG prospective hospital payment [Munoz] 612 (My)

Smoking policy in pediatric hospitals and wards [Jenista] 567 (My)

Survey of severe eye injuries in children [DeRespinis] 711 (Je)

Child Nutrition

Dietary advice: responsibility for monitoring [Finberg] 531 (My)

Measured energy expenditure in pediatric intensive care patients [Tilden] 490 (Ap)

Safety hazard with intravenous pumps (letter) [Schwartz] 1390 (De)

School breakfast program and school performance [Meyers] 1234 (Oc)

Child Nutrition Disorders

Growth failure: complication of dietary treatment of hypercholesterolemia [Lifshitz] 537 (My)

Child, Preschool

Choking on 'large' object: applications for regulation and practice (letter) [Meyers] 1132 (Oc)

Household electrical injuries in children: epidemiology and identification of available hazards [Baker] 59 (Ja)

Measles—Los Angeles County, California, 1988, leads from *MMWR*, 525 (My)

Playground-related injuries in preschool-aged children—United States, 1983-1987, leads from *MMWR*, 125 (Ja)

Unintentional injuries: risk factors in preschool children [Bourguet] 556 (My)

Child Psychology

Barriers to bicycle helmet use among children: results of focus groups with fourth, fifth, and sixth graders [Howland] 741 (Je)

Comment on 'pediatrician as consultant' (letter) [Levenson] 641, (reply) [Stickler] 642 (Je)

Evaluation of camp program for siblings of children with cancer [Sahler] 690 (Je)

Nightmares on Main Street [Schmitt] 649 (Je)

Chlamydia trachomatis

Chlamydia and adolescent girl: enzyme immunoassay as screening tool [Soren] 51 (Ja)

Clinical predictors of *Chlamydia trachomatis* endocervicitis in adolescent women: looking for right combination [Remafedi] 1437 (De)

Chlorhexidine

Epidemic methicillin-gentamicin-resistant *Staphylococcus aureus* in neonatal intensive care unit

[Reboli] 34 (Ja)

Choking see Airway Obstruction

Cholecystectomy

Cholecystectomy in sickle cell anemia (letter) [Gerry] 764 (Jy)

Cholesterol

Effect of weight control on lipid changes in obese children [Ejstein] 454 (Ap)

You are a preventive cardiologist: scope of pediatric preventive cardiology (letter) [Pegelow] 639 (Je)

Cholesterol LDL see Lipoproteins, LDL Cholesterol

Cholestyramine

Discretion advised when lowering serum lipid levels of children (letter) [Kazaneck] 11 (Ja)

Christmas Disease

Plasma support for surgery in premature infant with factor IX deficiency (letter) [Pegelow] 639 (Je)

Chromosome Abnormalities

Cutis verticis gyrata and chromosomal abnormalities (letter) [Marni] 269 (Mr); correction, 592 (My)

Chronic Disease

Computers in medicine: augmenting medical care in pediatric patients with chronic illnesses [Handler] 1021 (Se)

Cicatrix

Morphea [Iyer] 1353 (No)

Circumcision

Circumcision and urinary tract abnormalities (letters) [Rockney, Hopp] (reply) [Herzog] 1261, 1262 (No)

Urinary tract infections and circumcision: case-control study [Herzog] 348 (Mr)

Cirrhosis, Liver see Liver Cirrhosis

Citrates

Abnormal zinc content in human milk: risk for development of nutritional zinc deficiency in infants [Atkinson] 608 (My)

Clavulanic Acids

Comparison of amoxicillin and clavulanic acid (Augmentin) for treatment of nonbullous impetigo [Dagan] 916 (Au)

Cleft Lip

Does maternal smoking during pregnancy cause cleft lip and palate in offspring? [Khoury] 333 (Mr)

Ectrodactyly, ectodermal dysplasia, and clefting associated with thymic aplasia (letter) [Jhaveri] 12 (Ja)

Cleft Palate

Does maternal smoking during pregnancy cause cleft lip and palate in offspring? [Khoury] 333 (Mr)

Ectrodactyly, ectodermal dysplasia, and clefting associated with thymic aplasia (letter) [Jhaveri] 12 (Ja)

Clinical Clerkship see Education, Medical, Undergraduate

Clinical Competence

Documentation of student's clinical reasoning using computer simulation [Schwartz]; (editorial comment) [Allen] 575 (My)

Clinical Trials

Alternating sequential dosing with furosemide and ethacrynic acid in drug tolerance in newborn [Chemtob] 850 (Jy)

Clinical trial of single-dose intravenous gamma globulin in acute Kawasaki disease: preliminary report [Engle] 1300 (No)

Corticosteroids as adjunctive therapy in bacterial meningitis: meta-analysis of clinical trials [Havens] 1051 (Se)

Dexamethasone for children with bacterial meningitis: should it be routine therapy? [Kaplan] 290 (Mr)

Dexamethasone therapy for bacterial meningitis in infants and children [McCracken] 287 (Mr)

Effects of theophylline on behavior and learning in children with asthma [Rappaport] 368 (Mr)

Magnetic resonance imaging and dexamethasone therapy for bacterial meningitis [Lebel] 301 (Mr)

Methylphenidate in children with seizures and attention-deficit disorder [Feldman] 1081 (Se)

Nonphenylketonuric hyperphenylalaninemia [Lang] 1464 (De)

Predictors of trough serum gentamicin concentrations in neonates [Keyes] 1419 (De)

Prophylaxis of recurrent acute otitis media and middle-ear effusion: comparison of amoxicillin with sulfamethoxazole and trimethoprim [Principi] 1414 (De)

Treatment of group: critical review [Skolnik] 1045 (Se)

Use of intravenous immunoglobulin in treatment of neonatal sepsis (letter) [Kim] 1257 (No)

Clonidine

Diagnostic limitations of spontaneous growth hormone measurements in normally growing prepubertal children [Lanes] 1284 (No)

Clustering see Space-Time Clustering

Cocaine

Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)

Passive freebase cocaine ('crack') inhalation by infants and toddlers [Bateman] 25 (Ja)

Passive inhalation of marijuana, phencyclidine, and freebase cocaine ('crack') by infants (letter) [Schwartz] 644 (Je)

Perinatal outcome of infants exposed to cocaine and/or heroin in utero [Fulroth] 905 (Au)

Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (My)

Prevalence of drug use among applicants for military service—United States, June-December 1988, leads from *MMWR*, 1273 (No)

Take up warning on TAC (letter) [Mofenson] 519 (My)

Urine drug screening in mothers and newborns [Osterloh] 791 (Jy)

Cognition

Neurologic status and intracranial hemorrhage in very low-birth-weight preterm infants: outcome at 1 year and 5 years [Ford] 1186 (Oc)

Cognition Disorders

Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)

Neurofibromatosis type 1 (Recklinghausen's disease): neurologic and cognitive assessment with sibling controls [Eldridge] 833 (Jy)

Colic

Collagenous colitis in child (letter) [Busuttill] 998 (Se)

Colitis

Collagenous colitis in child (letter) [Busuttill] 998 (Se)

Gastrointestinal milk intolerance of infancy [Berezin] 361 (Mr)

Collagen

Collagenous colitis in child (letter) [Busuttill] 998 (Se)

Colonoscopy

Gastrointestinal milk intolerance of infancy [Berezin] 361 (Mr)

Colony-Forming Units, Hematopoietic see Hematopoietic Stem Cells

Colorado

Neonatal hyperbilirubinemia at high altitude [Leibson] 983 (Au)

Combined Modality Therapy

Use of intravenous immunoglobulin in treatment of neonatal sepsis (letter) [Kim] 1257 (No)

Commerce

Resident stress (letters) [Giardino, Welliver] 1129 (Oc)

Communication

Adolescent contraceptive use and parental notification [Demetriou] 1166 (Oc)

Advances in neonatal care (letter) [Goetzman] 441 (Ap)

Complement

Low serum complement levels in anorexia nervosa (letter) [Sigal] 1391, (reply) [Eichenfield] 1392 (De)

Complement Activation

Secondary disorders of complement system [Eichenfield] 595 (My)

Complement Fixation Tests

Toxoplasmosis needs evaluation: overview and proposals [Koskineemi] 724 (Je)

Complement Pathway, Alternative see Complement Activation

Complement Pathway, Classical see Complement Activation

Complement Proteins see Complement

Computer Simulation

Documentation of students' clinical reasoning using computer simulation [Schwartz] 575; (editorial comment) [Allen] 575 (My)

Computer Software see Software

Computers

Computer timidity: some thoughts [Arnold] 1020 (Se)

Computerized patient scheduling in outpatient residency practices [Quattlebaum] 1333 (No)

Computers in medicine: augmenting medical care in pediatric patients with chronic illnesses [Handler] 1021 (Se)

Incomplete immunizations and computer (letter) [Curro] 441 (Ap)

Condoms see Contraceptive Devices, Male

Conferences see Congresses

Congenital Defects see Abnormalities

Congresses

Current state of pertussis and pertussis vaccines: report on Fifth International Symposium on Pertussis [Fulginiti] 532 (My)

Conjunctivitis, Bacterial

Gonococcal conjunctivitis mimicking orbital cellulitis in young adolescent (letter) [Legido] 443 (Ap)

Connecticut
Epidemiology of cluster of Henoch-Schönlein purpura [Farley] 798 (Jy)

Constipation
Bubble gum bezoar [Truex] 253 (Fe)
Risk factors for infant botulism in United States [Spika] 828 (Jy)

Consultation see Referral and Consultation

Consumer Product Safety

You are a preventive cardiologist: scope of pediatric preventive cardiology [Strong] 1145 (Oc)

Health Maintenance Organizations

Impact of fever health education on clinic utilization [Robinson] 698 (Je)

Health Manpower

Pediatric marketplace [Martinez] 924 (Au)

Health Policy

Health care financing policy for hospitalized pediatric patients [Munoz] 312 (Mr)

Prospective reimbursement and pediatric services [Singleton] 292 (Mr)

Health Promotion

Resident stress (letters) [Giardino, Welliver] 1129 (Oc)

Health Resources

Mortality with increasing assisted ventilation of very-low-birth-weight infants [Doyle] 223 (Fe)

Health Services

Beware of overtreating children: [Cunningham] 786 (Jy)

DICE: nonclinical causes of overtreatment (letter) [Cunningham] 142 (Fe)

Health Services Misuse see Health Services

Health Services Needs and Demand see Health Services Research

Health Services Research

Model to determine feasibility of pediatric practice [Miller] 919 (Au)

Health Manpower

Pediatric marketplace [Martinez] 924 (Au)

Health Surveys

Adult immunization: knowledge, attitudes, and practices—DeKalb and Fulton Counties, Georgia, 1988, leads from *MMWR*, 281 (Mr)

Hearing Loss, Bilateral see Hearing Loss, Partial

Hearing Loss, Partial

Aminoglycoside ototoxicity in cystic fibrosis: evaluation by high-frequency audiometry [McRorie] 1328 (No)

Corticosteroids as adjunctive therapy in bacterial meningitis: meta-analysis of clinical trials [Havens] 1051 (Se)

Hearing Loss, Sensorineural

Dexamethasone for children with bacterial meningitis: should it be routine therapy? [Kaplan] 290 (Mr)

Dexamethasone therapy for bacterial meningitis in infants and children [McCracken] 287 (Mr)

Magnetic resonance imaging and dexamethasone therapy for bacterial meningitis [Lebel] 301 (Mr)

Otologic manifestations in congenital velopharyngeal insufficiency [Darr] 75 (Ja)

Hearing Tests

Neurological and developmental findings in children with cataracts [Pike] 706 (Je)

Heart Arrest

Failure of electrocardiographic monitoring to detect cardiac arrest in patients with pacemakers [Brownlee] 105 (Ja)

Hyperglycemic acidosis with mortality in Kearns-Sayre syndrome (letter) [Welch] 1135 (Oc)

Heart Atrium

Complex congenital heart disease after in vitro fer-

tilization (letter) [Marino] 1136 (Oc)

Heart Catheterization

Pulmonary hypertension and asthma in 2 patient with congenital heart disease [Rothman] 977 (Au)

Heart Defects, Congenital

Acute systemic organ injury in term infants after asphyxia [Perlman] 617 (My)

Cardiac malformations in relatives of infants with hypoplastic left-heart syndrome [Brenner] 149 (De)

Complex congenital heart disease after in vitro fertilization (letter) [Marino] 1136 (Oc)

Congenital cardiovascular malformations in twins and triplets from population-based study [Berj] 1461 (De)

Ebstein's anomaly and extracardiac defects [Sibert] 570 (My)

Patterns of cardiac care in infants with Down syndrome [Schneider] 363 (Mr)

Pulmonary hypertension and asthma in 2 patients with congenital heart disease [Rothman] 977 (Au)

Heart Diseases

Neonatal intensive care: at what price? [Bedrick] 451 (Ap)

Heart Enlargement

Late sudden unexpected deaths in hospitalized infants with bronchopulmonary dysplasia [Abma] 815 (Jy)

Heart Rate

Normative oscillometric blood pressure values in first 5 years in office setting [Park] 860 (Jy)

Racial differences in young children's blood pressure: responses to dynamic exercise [Treiber] 720 (Je)

Heart Septal Defects, Ventricular

Complex congenital heart disease after in vitro fertilization (letter) [Marino] 1136 (Oc)

Correction of atrioventricular septal defect [Ve] 1361 (No)

Heart Surgery

Patterns of cardiac care in infants with Down syndrome [Schneider] 363 (Mr)

Hellanthus

Sunflower seed bezoar presenting as diarrhea (letter) [Dent] 643 (Je)

Helmets see Protective Devices

Hemagglutinins

Efficacy and immunogenicity of acellular pertussis vaccine by manufacturer and patient age [Aoyama] 655 (Je)

Influenza vaccine composition recommendation for 1989-90 season, leads from *MMWR*, 768 (Jy)

Hemangioma

Hemangioma of thigh [Weisberg] 379 (Mr)

Hematologic Diseases

Hematologic syndrome of growth-retarded infant (letter) [Meberg] (reply) [Philip] 1260 (No)

Nonphenylketonuric hyperphenylalaninemia [Lang] 1464 (De)

Hematologic Tests

Clear heads and Bayesian tales: predictive value and coin toss? (letter) [Mauo] 1000 (reply) [Halperin, Brown] 1001 (Se)

Lead screening at pediatric teaching program [Edwards] 1455 (De)

Hematoma

Clinical indicators of intracranial lesion on computed tomographic scan in children with parietal skull fracture [Bonadio] 194 (Fe)

Hematopoietic Stem Cells

Hematologic syndrome of growth-retarded infant (letter) [Meberg] (reply) [Philip] 1260 (No)

Neonatal neutrophil host defense: prospects for immunologic enhancement during neonatal sepsis [Cairo] 40 (Ja)

Hematuria

Hyperuricosuria and microhematuria in childhood (letter) [Sánchez Bayle] 878 (Au)

Heme Oxygenase see Hydroxylases

Hemiplegia

Early diagnosis of spastic diplegia, spastic hemiplegia, and quadriplegia [Harris] 1356 (No)

Hemodynamics

Acute changes in renal function associated with deferoxamine therapy [Koren] 1077 (Se)

Hemolysis

Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)

Hemolytic-Uremic Syndrome

Gastrointestinal manifestations of hemolytic urmic syndrome [Poe] 1481 (De)

Hemophilia

Acquired immunodeficiency syndrome among adolescents: case surveillance profiles in New York City and rest of United States [Vermund] 1220 (Oc)

Postdelivery head bleeding in hemophilic neonate causes and management [Kletzel] 1107 (Se)

Pediatricians' recommendations for antipyretic agents with DTP immunizations: survey of current practice (letter) [Flanagan] 517 (My)

Recommendations of Immunization Practices Advisory Committee (ACIP): general recommendations on immunization, leads from *MMWR*, 1013 (Se)

Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)

Rubella and congenital rubella syndrome—United States, 1985-1988, leads from *MMWR*, 893 (Au)

Updating immunization status at discharge (letter) 879 [Walterspiel] (Au)

Immunization, Passive

Neonatal neutrophil host defense: prospects for immunologic enhancement during neonatal sepsis [Cairo] 40 (Ja)

Immunization Schedule

Incomplete immunizations and computer (letter) [Curro] 441 (Ap)

Immunoassay, Enzyme see Immunoassay Techniques

Immunocompetence

Recommendations of Immunization Practices Advisory Committee (ACIP): general recommendations on immunization, leads from *MMWR*, 1013 (Se)

Immunoassay Techniques

Chlamydia and adolescent girl: enzyme immunoassay as screening tool [Soren] 51 (Ja)

Immunofluorometric Assay see Fluorimmunoassay

Immunoglobulin Therapy see Immunization, Passive

Immunoglobulins

Anti-*Staphylococcus aureus* IgE antibodies for diagnosis of hyperimmunoglobulinemia E-recurrent infection syndrome in infancy [Lavoie] 1038 (Se)

Kawasaki disease with thrombocytosis followed by thrombocytopenia purpura in same patient (letter) [Lipnick] 139 (Fe)

Recommendations of Immunization Practices Advisory Committee (ACIP): general recommendations on immunization, leads from *MMWR*, 1013 (Se)

Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)

Reconsideration of IgM-enriched intravenous immunoglobulin for neonatal sepsis (letter) [Hall] (reply) [Haque] 766 (Jy)

Use of intravenous immunoglobulin in treatment of neonatal sepsis (letter) [Kim] 1257 (No)

Immunologic Deficiency Syndromes

Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)

Impetigo

Comparison of amoxicillin and clavulanic acid (Augmentin) for treatment of nonbullous impetigo [Dagan] 916 (Au)

Income

Acute remunerative neurology [Ferry] 898 (Au)

Incontinent Pigment see Pigmentation Disorders

Indiana, North American

Human plague—United States, 1988, leads from *MMWR*, 145 (Fe)

Indomethacin

Plasma support for surgery in premature infant with factor IX deficiency (letter) [Pegelow] 639 (Je)

Pulmonary function in preterm infants following treatment with intravenous indomethacin [Krauss] 78 (Ja)

Infant

Anti-*Staphylococcus aureus* IgE antibodies for diagnosis of hyperimmunoglobulinemia E-recurrent infection syndrome in infancy [Lavoie] 1038 (Se)

Cardiac malformations in relatives of infants with hypoplastic left-heart syndrome [Brenner] 1492 (De)

Cardiorespiratory patterns during alarms in infants using apnea/bradycardia monitors [Nathanson] 476 (Ap)

Cast bronchitis in infants and children [Pérez-Soler] 1024 (Se)

Choking on 'large' object: applications for regulation and practice (letter) [Meyers] 1132 (Oc)

Circumcision and urinary tract abnormalities (letters) [Rockney, Hopp] (reply) [Herzog] 1261, 1262 (No)

Computed tomography in diagnosis of osteoid osteoma in infancy (letter) [Fletaj] 1000 (Se)

Diagnosis of neurofibromatosis-1 in child under age of 6 years [Obringer] 717 (Je)

Emergence of isolates resistant to ampicillin [Rupar] 1033 (Se)

Evaluation of vomiting infant [Foley] 660 (Je)

Gastroesophageal reflux-induced hypoxemia in infants with apparent life-threatening event [See] 951 (Au)

Gastroesophageal reflux to proximal esophagus: infants with bronchopulmonary dysplasia [Siddell] 1103 (Se)

Gastrointestinal milk intolerance of infancy [Berzin] 361 (Mr)

Klebsiella pneumoniae bacteremia in children: cases in 10 years [Bonadio] 1061 (Se)

Mucopolysaccharidosis I presenting with endocardial fibroelastosis of infancy [Stephan] 782 (Jy)

Normative oscillometric blood pressure values first 5 years in office setting [Park] 860 (Jy)

Passive inhalation of marijuana, phencyclidine, a freebase cocaine ('crack') by infants (letter) [Schwartz] 644 (Je)

Patterns of cardiac care in infants with Down syndrome [Schneider] 363 (Mr)

Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (M)

Pulse oximetry in methemoglobinemia [Watch] 845 (Jy)

Respiratory syncytial virus outbreak on American Samoa: evaluation of risk factors [Hayes] 316 (Mr)

Rubella and congenital rubella syndrome—United States, 1985-1988, leads from *MMWR*, 893 (Au)

Simultaneous transient hyperphosphatasemia set of twins (letter) [Kraut] 881 (Au)

Toxic shock syndrome caused by strain of *Staphylococcus aureus* that produces enterotoxin C but not toxic shock syndrome toxin-1 [Rizkallah] 848 (Jy)

Urinary tract infections and circumcision: case-control study [Herzog] 348 (Mr)

Infant Care

Advances in neonatal care (letter) [Goetzman] 4 (Ap)

Mucocutaneous lymph node syndrome: is the relationship to mercury exposure? (letter) [Aschner] 1133, (reply) [Krowchuk] 1134 (Oc)

Infant Food

Breast-feeding pattern among Indo-Chinese immigrants in northern California [Romero-Gwyn] 804 (Jy)

Infant sleep and bedtime cereal [Mackinn] 1066 (S)

Manganese absorption from human milk, cow milk, and infant formulas in humans [Davidso] 823 (Jy)

'Mangoism' (letter) [Palevsky] 1131 (Oc)

Partition of nitrogen intake and excretion in low-birth-weight infants [Donovan] 1485 (De)

Risk factors for infant botulism in United States [Spika] 828 (Jy)

Sucking and breathing patterns during breast- and bottle-feeding in term neonates: effects of nutrient delivery and composition [Mathew] 588 (My)

Infant Health Services see Child Health Services

Infant, Low Birth Weight

Abnormal zinc content in human milk: risk for development of nutritional zinc deficiency in infant [Atkinson] 608 (My)

Assessment of neurodevelopmental outcome surfactant-replacement therapy (letter) [Lankamp] 762, (reply) [Vaucher] 763 (Jy)

Breath hydrogen excretion as screening test for early diagnosis of necrotizing enterocolitis [Cheu] 156 (Fe)

Changes in nutritional management and outcome very-low-birth-weight infants [Georgieff] 82 (J)

Comparison of airway pathologic lesions with high frequency jet or conventional ventilation [Pola] 228 (Fe)

Differential effects of intrauterine and postnatal brain growth failure in infants of very low birth weight [Hack] 63 (Ja)

Early diagnosis of spastic diplegia, spastic hemiplegia, and quadriplegia [Harris] 1356 (No)

Epidemic methicillin-gentamicin-resistant *Staphylococcus aureus* in neonatal intensive care unit [Reboli] 34 (Ja)

Home oxygen therapy for chronic lung disease extremely low-birth-weight infants [Hudak] 3 (Mr)

Sexually transmitted diseases curriculum in adolescent medicine [Johnson] 1073 (Se)

Stress experienced during pediatric residency training program (letter) [Schubert] 1257 (No)

Stress experienced during pediatric residency training: its causes, consequences, recognition, and solutions [Hoekelman] 177 (Fe)

Telephone etiquette: telephone, one of physician's most necessary and, at times, most hated devices (letter) [Stickler] 520 (My)

Thoughts on residency education, 1969-1989 [Roberts] 294 (Mr)

Interpersonal Relations

Adolescent heterosexual relationship and its association with sexual and contraceptive behavior of black girls [DuRant] 1467 (De)

Intestinal Absorption

Vitamin K absorption capacity and its association with vitamin K deficiency [Shinzawa] 686 (Je)

Intestinal Diseases

International adoption: introduction for physicians [Hostetter] 325 (Mr)

Intestinal Obstruction

Jejunal stenosis: delayed complication of lap-type seat belt injury (letter) [Weinberg] 1392 (De)

Intracranial Pressure

Ameliorating effect of lumbar puncture in viral meningitis [Jaffe] 682 (Je)

Intraocular Pressure

Benign cause of intermittent bradycardia of prematurity (letter) [Reif] 270 (Mr)

Intrauterine Growth Retardation see Fetal Growth Retardation

Intubation, Endotracheal see Intubation, Intratracheal

Intubation, Intratracheal

Fiberoptic bronchoscopy in treatment of intubated neonates [Shinwell] 1064 (Se)

Prevention of accidental extubations in newborns (letter) [Liu] 880 (Au)

Inulin

Acute changes in renal function associated with deferoxamine therapy [Koren] 1077 (Se)

Iron

Abnormal zinc content in human milk: risk for development of nutritional zinc deficiency in infants [Atkinson] 608 (My)

Interactions of alcohol and nutrition (letter) [da Cunha Ferreira] 519 (My); correction, 1110 (Se)

Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)

Manganese absorption from human milk, cow's milk, and infant formulas in humans [Davidsson] 823 (Jy)

Ischemia

Ischemic injury and necrotizing tracheobronchitis (letter) [Wiswell] 1259 (No)

Symmetrical thalamic degeneration with calcifications of infancy [DiMario] 1056 (Se)

Islands of Langerhans

Hyperglycemic acidosis with mortality in Kearns-Sayre syndrome (letter) [Welch] 1135 (Oc)

Isopterenol

Use of adrenergic bronchodilators by pediatric allergists and pulmonologists [Newcomb] 481 (Ap)

Israel

Poliovirus vaccine policy: another perspective [Katz] 1007 (Se)

IUGR see Fetal Growth Retardation

J

Jamaica

1-month elective in international health for senior pediatric residents (letter) [Duncan] 1389 (De)

Japan

Efficacy and immunogenicity of acellular pertussis vaccine by manufacturer and patient age [Aoyama] 656 (Je)

Jaundice, Neonatal

Neonatal hyperbilirubinemia at high altitude [Leibson] 983 (Au)

Use of metalloporphyrins for chemoprevention of neonatal jaundice [Stevenson] 353 (Mr)

Jejunum

Jejunal stenosis: delayed complication of lap-type seat belt injury (letter) [Weinberg] 1392 (De)

Job's Syndrome, see Phagocyte Bactericidal Dysfunction

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Neonatal intensive care: at what price? [Bedrick] 451 (Ap)

Kawasaki Disease see Mucocutaneous Lymph Node Syndrome

Kearns-Sayre-Shy-Daroff Syndrome see Ophthalmoplegia

Ketones

Relative carnitine insufficiency in children with type I diabetes mellitus [Winter] 1337 (No)

Kidney

Acute systemic organ injury in term infants after asphyxia [Perlman] 317 (My)

Does methylprednisolone pulse therapy deteriorate course of rapidly progressive IgA nephropathy? (letter) [Itami] 441, (reply) [Welch] 442 (Ap)

Lack of associated renal anomalies in familial polythelia (letter) [Bortz] 883 (Au)

Kidney Diseases

Protein intake and renal function in children [Nakano] 160 (Fe)

Single umbilical artery: report of 159 cases [Leung] 108 (Ja)

Kidney Failure, Acute

Acute changes in renal function associated with deferoxamine therapy [Koren] 1077 (Se)

Kidney Failure, Chronic

Patient with IgA nephropathy (letter) [Cachero] (reply) [Welch] 138 (Fe)

Kidney Function Tests

Acute changes in renal function associated with deferoxamine therapy [Koren] 1077 (Se)

Kidney Tubules

Protein intake and renal function in children [Nakano] 160 (Fe)

Klebsiella pneumoniae

Klebsiella pneumoniae bacteremia in children: 57 cases in 10 years [Bonadio] 1061 (Se)

L

Lactic Acidosis see Acidosis, Lactic

Lactoferrin see Lactoglobulins

Lactoglobulins

Partition of nitrogen intake and excretion in low-birth-weight infants [Donovan] 1485 (De)

Language

Praise for useful words [Brown] 770 (Jy)

Laos

Breast-feeding pattern among Indochinese immigrants in northern California [Romero-Gwynn] 804 (Jy)

Laryngitis

Treatment of croup: critical review [Skolnik] 1045 (Se)

Larynx

Congenital laryngeal atresia [Fang] 625 (My)

Latex Agglutination Tests see Latex Fixation Tests

Latex Fixation Tests

Diagnosis of group A, beta-hemolytic streptococcal pharyngitis in office setting: rapid latex test vs throat culture [Taubman] 102 (Ja)

Diagnosis of group A, beta-hemolytic streptococcal pharyngitis in office setting (letter) [Kellogg] (reply) [Taubman] 761 (Jy)

LDL Cholesterol see Lipoproteins, LDL Cholesterol

Lead Poisoning

Height and weight following lead poisoning in childhood [Sachs] 820 (Jy)

Lead screening at pediatric teaching programs [Bdeards] 1455 (De)

Learning

Effects of theophylline on behavior and learning in children with asthma [Rappaport] 368 (Mr)

Learning Disorders

Neurofibromatosis type 1 (Recklinghausen's disease): neurologic and cognitive assessment with sibling controls [Elkridge] 833 (Jy)

Leg

Purpuric rashes in cystic fibrosis [Schidlow] 1030 (Se)

Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)

Legal Medicine see Forensic Medicine

Legislation

Child passenger safety: past, present, and future [Christoffel] 1271 (No)

Length of Stay

Pediatric patients, race, and DRG prospective hospital payment [Munoz] 612 (My)

Safety of newborn discharge in less than 36 hours in indigent population [Conrad] 98 (Ja)

Leukemia

Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)

Transient erythroblastopenia of childhood: review of 26 cases and reassessment of indications for bone marrow aspiration [Hays] 605 (My)

Hematologic syndrome of growth-retarded infant (letter) [Meberg] (reply) [Philip] 1260 (No)

Prognostic factors and life expectancy in child with acquired immunodeficiency syndrome a *Pneumocystis carinii* pneumonia [Bernste] 775 (Jy)

Levocardia see Heart Defects, Congenital

LH

Diagnostic value of testosterone therapy in bc with delayed puberty [Kaplowitz] 116 (Ja)

Onset of sperm reproduction in pubertal boys: relationship to gonadotropin excretion [Kulin] 190 (I)

LH-FSH Releasing Hormone

Puberty in syndrome of septo-optic dysplasia [Hina] 186 (Fe)

LH Releasing Hormone see LH-FSH Releasing Hormone

Life Change Events

Stress experienced during pediatric residency training: its causes, consequences, recognition and solutions [Hoekelman] 177 (Fe)

Life Expectancy

Prognostic factors and life expectancy in child with acquired immunodeficiency syndrome a *Pneumocystis carinii* pneumonia [Bernste] 775 (Jy)

Lipids

Abnormal zinc content in human milk: risk for development of nutritional zinc deficiency in infants [Atkinson] 608 (My)

Effect of weight control on lipid changes in obese children [Epstein] 454 (Ap)

Lipochondrodystrophy

Mucopolysaccharidosis I presenting with endocardial fibroelastosis of infancy [Stephan] 782 (Jy)

Lipodystrophy

Secondary disorders of complement system [Chenfield] 595 (My)

Lipoproteins, HDL

Effect of weight control on lipid changes in obese children [Epstein] 454 (Ap)

Lipoproteins, HDL Cholesterol

Dietary advice: responsibility for monitoring [Fberg] 531 (My)

Effect of weight control on lipid changes in obese children [Epstein] 454 (Ap)

Lipoproteins, LDL Cholesterol

Discretion advised when lowering serum lipid levels of children (letter) [Kazanecki] 11 (Ja)

Little's Disease see Cerebral Palsy

Liver

Marked transient alkaline phosphatemia following pediatric liver transplantation [Koneru] 669 (J)

Liver Abscess

Morbidity and mortality in children with pyogenic liver abscess [Pineiro-Carrero] 1424 (De)

Pylephlebitis secondary to unsuspected appendiceal rupture [Giuliano] 1099 (Se)

Liver Cirrhosis

Pulmonary arteriovenous shunting in child with cirrhosis of liver [Crary] 749 (Je)

Secondary disorders of complement system [Chenfield] 595 (My)

Liver Diseases

Secondary disorders of complement system [Chenfield] 595 (My)

Location see Professional Practice

Locus of Control see Internal-External Control

Los Angeles

Measles—Los Angeles County, California, 19 leads from *MMWR*, 525 (My)

LSD see Lysergic Acid Diethylamide

Lumbar Puncture see Spinal Puncture

Luminescence

Increased phagocytic cell chemiluminescence in patients with cystic fibrosis [Roberts] 944 (Au)

Luminol see Pyridazines

Lung

Right-upper-lobe esophageal bronchus (w VATER anomalies) [Davies] 251 (Fe)

Traumatic pulmonary pseudocyst [Co] 841 (Jy)

Lung Capacities see Lung Volume Measurement Lung Diseases

Home oxygen therapy for chronic lung disease extremely low-birth-weight infants [Hudak] (Mr)

Hypertrophic pulmonary osteoarthropathy [Bolic] 747 (Je)

Regulation of oxygen concentration delivered infants via nasal cannulas [Vain] 1458 (De)

Lung Diseases, Obstructive

Effect of respiratory viral infections on patients with cystic fibrosis [Ramsey] 662 (Je)

Lung Volume Measurements

Effect of respiratory viral infections on patients with cystic fibrosis [Ramsey] 662 (Je)

Luteinizing Hormone see LH

Lymphadenitis
Cat-scratch disease therapy (letter) [Collipp] 1261 (No)

Lymphadenopathy-Associated Virus see HIV

Lymphedema
Cutis verticis gyrata and chromosomal abnormalities (letter) [Marini] 269 (Mr); correction, 592 (My)

Lymphocytes
Prognostic factors and life expectancy in children with acquired immunodeficiency syndrome and *Pneumocystis carinii* pneumonia [Bernstein] 775 (Jy)

T4 Lymphocytes
Prognostic factors and life expectancy in children with acquired immunodeficiency syndrome and *Pneumocystis carinii* pneumonia [Bernstein] 775 (Jy)

Lymphoproliferative Disorders
Secondary disorders of complement system [Eichenfield] 595 (My)

Lysergic Acid Diethylamide
Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)

M

Magnetic Resonance Imaging
Dacitis [Magera] 1479 (De)
Hemangioma of thigh [Weisberg] 379 (Mr)
Magnetic resonance imaging and dexamethasone therapy for bacterial meningitis [Lebel] 301 (Mr)
Osteonecrosis of femoral head diagnosed by magnetic resonance imaging [Barzel] 623 (My)
Perinatal abnormalities and subhypothalamic bright spot on magnetic resonance imaging in pituitary dwarfs (letter) [Okabe] 1394 (De)
Subhypothalamic high-intensity signals identified by magnetic resonance imaging in children with idiopathic anterior hypopituitarism: evidence suggestive of 'ectopic' posterior pituitary gland [Root] 366 (Mr)

Main nutrition see Nutrition Disorders

Malpractice
Perinatal asphyxia and cerebral palsy: fact, fiction, or legal prediction? [Bedrick] 1139 (Oc)

Mammary Glands see Breast

Manganese
Manganese absorption from human milk, cow's milk, and infant formulas in humans [Davidsson] 823 (Jy)

Mannitol
Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)

Marijuana Abuse see Cannabis Abuse

Marijuana Smoking
Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)
Passive inhalation of marijuana, phenylcyclidine, and freebase cocaine ('crack') by infants (letter) [Schwartz] 644 (Je)
Prevalence of drug use among applicants for military service—United States, June–December 1988, leads from *MMWR*, 1273 (No)

Marketing of Health Services
Pediatric marketplace [Martinez] 924 (Au)

Marriage
Being just a husband is no fun [Stiehm] 1401 (De)

Mass Screening
Breath hydrogen excretion as screening test for early diagnosis of necrotizing enterocolitis [Cheu] 156 (Fe)
Chlamydia and adolescent girl: enzyme immunoassay as screening tool [Soren] 51 (Ja)
Clear heads and Bayesian tales: predictive value and coin toss? (letter) [Mauro] 1000 (replies) [Halperin, Brown] 1001 (Se)
Leading screening at pediatric teaching programs [Edwards] 1455 (De)
You are a preventive cardiologist: scope of pediatric preventive cardiology [Strong] 1145 (Oc)

Mastocytosis
Reticulated pattern of telangiectasias on infant arm; urticaria pigmentosa; hyperpigmentation; incontinentia pigmenti [Cohen] 255 (Fe)

Maternal Age
TEARS: does domestic violence play role? (letter) [Rimsza] 137 (Fe)

Maternal-Fetal Exchange
Human immunodeficiency virus-infected infant: diagnostic dilemma [Ochs] 1188 (Oc)
Natural history and serologic diagnosis of infants born to human immunodeficiency virus-infected women [Johnson] 1147 (Oc)

Mathematics
Determinants of school performance in children with chronic asthma [Gutstadt] 471 (Ap)

Maximal Midexpiratory Flow Rate see Forced Expiratory Flow Rates

Measles
Antiviral drugs in pediatrics [Balfour] 1307 (No)
Current trends, measles—United States, 1988, leads from *MMWR*, 1395 (De)
Measles—Los Angeles County, California, 1988, leads from *MMWR*, 525 (My)
Measles outbreak—Chicago, 1989, leads from *MMWR*, 1273 (No)
Measles Vaccine
Measles outbreak—Chicago, 1989, leads from *MMWR*, 1273 (No)

Mediastinal Cyst
Extrapleural effusion of retropharyngeal origin [Martinet] 1207 (Oc)

Mediastinal Emphysema
Pneumomediastinum and subcutaneous emphysema caused by diabetic hyperpnea [Bullaboy] 93 (Ja)
Traumatic hypopharyngeal pseudodiverticulum [Pramanik] 55 (Ja)

Medical see Medical Assistance, Title 19

Medical Assistance, Title 19
Health care financing policy for hospitalized pediatric patients [Munoz] 312 (Mr)
Prospective reimbursement and pediatric services [Singleton] 292 (Mr)

Medical Audit
Drug errors and incidents in neonatal intensive care unit: quality assurance activity [Vincer] 737 (Je)

Medical Devices see Equipment and Supplies

Medical Examiners see Coroners and Medical Examiners

Medical Indigency
Safety of newborn discharge in less than 36 hours in indigent population [Conrad] 98 (Ja)
Updating immunization status at discharge (letter) [Walterspiel] 879 (Au)

Medical Records
Computers in medicine: augmenting medical care in pediatric patients with chronic illnesses [Handler] 1021 (Se)
Incomplete immunizations and computer (letter) [Curro] 441 (Ap)
Informed consent for lumbar puncture [Botkin] 899 (Au)
International adoption: introduction for physicians [Hostetter] 325 (Mr)
Management of diabetes in pediatric resident continuity clinics [Kronz] 1173 (Oc)
Updating immunization status at discharge (letter) [Walterspiel] 879 (Au)

Medication Errors
Drug errors and incidents in neonatal intensive care unit: quality assurance activity [Vincer] 737 (Je)

Memory Disorders
Short-term memory impairment in cannabis-dependent adolescents [Schwartz] 1214 (Oc)

Memory, Short-Term
Short-term memory impairment in cannabis-dependent adolescents [Schwartz] 1214 (Oc)

Men
Firearm ownership among nonurban adolescents [Sadowski] 1410 (De)

Meningitis
Corticosteroids as adjunctive therapy in bacterial meningitis: meta-analysis of clinical trials [Havens] 1051 (Se)
Haemophilus influenzae type e (biotype IV) meningitis (letter) [Marshall] 9 (Ja)
Informed consent for lumbar puncture [Botkin] 899 (Au)
Magnetic resonance imaging and dexamethasone therapy for bacterial meningitis [Lebel] 301 (Mr)
Neonatal *Staphylococcus epidermidis* meningitis with unremarkable CSF examination results [Gruskas] 580 (My)

Meningitis, Haemophilus
Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)
Dexamethasone for children with bacterial meningitis: should it be routine therapy? [Kaplan] 290 (Mr)
Dexamethasone therapy for bacterial meningitis in infants and children [McCracken] 287 (Mr)

Meningitis, Pneumococcal
Dexamethasone for children with bacterial meningitis: should it be routine therapy? [Kaplan] 290 (Mr)
Dexamethasone therapy for bacterial meningitis in infants and children [McCracken] 287 (Mr)

Meningitis, Viral
Ameliorating effect of lumbar puncture in viral meningitis [Jaffe] 682 (Je)
Dexamethasone for children with bacterial men-

ingitis: should it be routine therapy? [Kaplan] 290 (Mr)

Menstruation
Iron deficiency in athletes: insights from high school swimmers [Lowland] 197 (Fe)
Long-term outcome of adolescents with anorexia nervosa [Kreipe] 1522 (No)

Mental Disorders
Attitudes toward mental illness prevention in routine pediatric practice [Yager] 1089 (Se)
Parent, teacher, child: trilateral approach to attention deficit disorder [Cohen] 1229 (Oc)

Mental Retardation
Cutis verticis gyrata and chromosomal abnormalities (letter) [Marini] 269 (Mr); correction, 592 (My)

Mercury Poisoning
Mucocutaneous lymph node syndrome: is there relationship to mercury exposure? (letter) [Aschner] 1133, (reply) [Krowchuk] 1134 (Oc)

Mesenchymoma
Congenital rhabdomyomatous mesenchymal hamartoma of skin [Levkoff] 963 (Au)

Meta-Analysis
Corticosteroids as adjunctive therapy in bacterial meningitis: meta-analysis of clinical trials [Havens] 1051 (Se)

Metabolic Clearance Rate
Acute changes in renal function associated with deferoxamine therapy [Koren] 1077 (Se)

Metabolism
Age, gender, and metabolic control in children and adolescents with diabetes (letter) [Zimet] 1134 (Oc)

Metalloporphyrins
Use of metalloporphyrins for chemoprevention of neonatal jaundice [Stevenson] 353 (Mr)

Metaplasia
Cyst bronchitis in infants and children [Pérez-Soler] 1024 (Se)

Metaproteolol see O-ciprenaline

Methadone
Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (My)
Urine drug screening in mothers and newborns [Osterloh] 791 (Jy)

Methemoglobinemia
Pulse oximetry in methemoglobinemia [Watcha] 845 (Jy)

Methicillin
Epidemic methicillin-gentamicin-resistant *Staphylococcus aureus* in neonatal intensive care unit [Reboli] 34 (Ja)

Methylene Chloride see Hydrocarbons, Chlorinated

Methylmercury Compounds
Mucocutaneous lymph node syndrome: is there relationship to mercury exposure? (letter) [Aschner] 1133, (reply) [Krowchuk] 1134 (Oc)

Methylphenidate
Methylphenidate in children with seizures and attention-deficit disorder [Feldman] 1081 (Se)
Parent, teacher, child: trilateral approach to attention deficit disorder [Cohen] 1229 (Oc)

Methylprednisolone
Determinants of school performance in children with chronic asthma [Gutstadt] 471 (Ap)
Does methylprednisolone pulse therapy deteriorate course of rapidly progressive IgA nephropathy? (letter) [Itami] 441, (reply) [Welch] 442 (Ap)

Microcephaly
Growth hormone treatment in children with sporadic primary microcephaly [Spadoni] 1282 (No)
Perinatal outcome of infants exposed to cocaine and/or heroin in utero [Fulroth] 905 (Au)

Microcomputers
Computer timidity: some thoughts [Arnold] 1020 (Se)

Military Personnel
Prevalence of drug use among applicants for military service—United States, June–December 1988, leads from *MMWR*, 1273 (No)

Milk
Gastrointestinal milk intolerance of infancy [Berezin] 361 (Mr)
Hypophosphatemia in breast-fed low-birth-weight infants following initial hospital discharge [Hall] 1191 (Oc)
Manganese absorption from human milk, cow's milk, and infant formulas in humans [Davidsson] 823 (Jy)

Milk, Human
Abnormal zinc content in human milk: risk for development of nutritional zinc deficiency in infants [Atkinson] 608 (My)
Manganese absorption from human milk, cow's milk, and infant formulas in humans [Davidsson] 823 (Jy)
Partition of nitrogen intake and excretion in low-birth-weight infants [Donovan] 1485 (De)
Sucking and breathing patterns during breast- and

bottle-feeding in term neonates: effects of nutrient delivery and composition [Mathew] 588 (My)

Minerals
 Bone mineral content in black and white children 1 to 6 years of age: early appearance of race and sex differences [Li] 1346 (No)
 Bone mineral status in hypopituitarism (letter) [Arisaka] 272 (Mr)

Missouri
 Aquarium-associated *Plesiomonas shigelloides* infection—Missouri, leads from *MMWR*, 1396 (De)

Monitoring, Physiologic
 Cardiorespiratory patterns during alarms in infants using apnea/bradycardia monitors [Nathan] 476 (Ap)
 Gastroesophageal reflux-induced hypoxemia in infants with apparent life-threatening event(s) [See] 951 (Au)

Monocytes
 Increased phagocytic cell chemiluminescence in patients with cystic fibrosis [Roberts] 944 (Au)

Mood see Affect

Morbidity
 Morbidity and mortality in children with pyogenic liver abscess [Pineiro-Carrero] 1424 (De)

MORBIDITY AND MORTALITY REPORT
 Leads from *MMWR*, 125 (Ja), 145 (Fe), 281 (Mr), 447 (Ap), 525 (My), 645 (Je), 767 (Jy), 893 (Au), 1013 (Se), 1141 (Oc), 1273 (No), 1395 (De)

Morphea see Scleroderma, Circumscribed

Mortality
 Circumstances surrounding deaths of children due to asthma: case control study [Miller] 1294 (No)
Klebsiella pneumoniae bacteremia in children: 57 cases in 10 years [Bonadio] 1061 (Se)
 Morbidity and mortality in children with pyogenic liver abscess [Pineiro-Carrero] 1424 (De)
 Mortality with increasing assisted ventilation of very-low-birth-weight infants [Doyle] 223 (Fe)
 Prognostic factors and life expectancy in children with acquired immunodeficiency syndrome and *Pneumocystis carinii* pneumonia [Bernstein] 775 (Jy)
 Unintentional poisoning mortality—United States, 1980-1986, leads from *MMWR*, 645 (Je)

Mothers
 Pediatrician as mother (letter) [Furman] 638 (Je)
 Urine drug screening in mothers and newborns [Osterloh] 791 (Jy)

Motion Pictures
 Nightmares on Main Street [Schmitt] 649 (Je)

Motor Activity
 Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)

Mouth Breathing
 Sucking and breathing patterns during breast- and bottle-feeding in term neonates: effects of nutrient delivery and composition [Mathew] 588 (My)

Mucocutaneous Lymph Node Syndrome
 Clinical trial of single-dose intravenous gamma globulin in acute Kawasaki disease: preliminary report [Engle] 1300 (No)
 Kawasaki disease with thrombocytosis followed by thrombocytopenia purpura in same patient (letter) [Lipnick] 139 (Fe)
 Mucocutaneous lymph node syndrome: is there relationship to mercury exposure? (letter) [Aschner] 1133, (reply) [Krowchuk] 1134 (Oc)
 Mucopolysaccharidosis 1 see *Lipochondrodystrophy*

Mumps Vaccine
 Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)

Munchausen Syndrome
 Polymicrobial bacteremia and child abuse (letter) [Amir] 444 (Ap)

Muscles
 Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)

Mycoplasma pneumoniae
 Effect of respiratory viral infections on patients with cystic fibrosis [Ramsey] 662 (Je)

Myocardial Contraction
 Exercise-induced differences in cardiac output, blood pressure, and systemic vascular resistance in healthy biracial population of 10-year-old boys [Arensman] 212 (Fe)

Myoclonic Jerking, Massive see Spasms, Infantile

Myositis
 Pyomyositis in child with acquired immunodeficiency syndrome: patient report and brief review [Raphael] 779 (Jy)

N

Narcotics
 Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (My)

Nasal Polyps
 Nasal septal abscess; inflammatory nasal polyps; intranasal glioma [Wiatrak] 501 (Ap)

Nasal Septum
 Nasal septal abscess; inflammatory nasal polyps; intranasal glioma [Wiatrak] 501 (Ap)

National Swimming Pool Safety Committee
 Injury prevention: drowning (letter) [Smith] (reply) [Noyes] 272 (Mr)

Nebulizers and Vaporizers
 Efficacy and safety of home nebulizer therapy for children with asthma [Zimo] 205 (Fe)
 Experience with metered-dose inhaler with spacer in pediatric emergency department [Benton] 878 (Je)

Neck
 Extrapleural effusion of retropharyngeal origin [Martinot] 1207 (Oc)

Necrosis
 Comparison of airway pathologic lesions after high-frequency jet or conventional ventilation [Polak] 228 (Fe)
 Ischemic injury and necrotizing tracheobronchitis (letter) [Wiswell] 1259 (No)

Needles
 Recommendations of Immunization Practices Advisory Committee (ACIP): general recommendations on immunization, leads from *MMWR*, 1013 (Se)

Neisseria gonorrhoeae
 Gonococcal conjunctivitis mimicking orbital cellulitis in young adolescent (letter) [Legido] 443 (Ap)

Neomycin
 Recommendations of Immunization Practices Advisory Committee (ACIP) mumps prevention, leads from *MMWR*, 1141 (Oc)

Neonatal Abstinence Syndrome
 Perinatal outcome of infants exposed to cocaine and/or heroin in utero [Fulroth] 905 (Au)

Neonatology
 Advances in neonatal care (letter) [Goetzman] 441 (Ap)

Neoplasms
 Diagnosis of neurofibromatosis-1 in child under age of 6 years [Obringer] 717 (Je)
 Evaluation of camp program for siblings of children with cancer [Sahler] 690 (Je)

Nephrectomy
 Bubble gum bezoar [Truex] 253 (Fe)

Nephritis
 Secondary disorders of complement system [Eichenfield] 595 (My)

Nephroblastoma
 Bubble gum bezoar [Truex] 253 (Fe)

Nephropathy IgA see Glomerulonephritis, IgA

Nephrosis, Lipoid
 Parent-child minimal change nephrotic syndrome (letter) [Leung] 442 (Ap)

Nephrotic Syndrome
 Insulinlike growth factors in patients with active nephrotic syndrome [Garin] 865 (Jy)

Nephrotic Syndrome, Minimal Change see Nephrosis, Lipoid

Neural Crest
 Hirschsprung's disease and ocular autonomic nerve function (letter) [O'Connor] 1137 (Oc)

Neuraminidase
 Influenza vaccine composition recommendation for 1989-90 season, leads from *MMWR*, 768 (Jy)

Neurofibromatosis
 Diagnosis of neurofibromatosis-1 in child under age of 6 years [Obringer] 717 (Je)
 Neurofibromatosis type 1 (Recklinghausen's disease): neurologic and cognitive assessment with sibling controls [Eldridge] 833 (Jy)

Neurologic Examination
 Changes in nutritional management and outcome of very-low-birth-weight infants [Georgieff] 82 (Ja)
 Neurofibromatosis type 1 (Recklinghausen's disease): neurologic and cognitive assessment with sibling controls [Eldridge] 833 (Jy)
 Neurologic status and intracranial hemorrhage in very-low-birth-weight preterm infants: outcome at 1 year and 5 years [Ford] 1186 (Oc)
 Neurological and developmental findings in children with cataracts [Pike] 706 (Je)
 Reye's syndrome: reappraisal of diagnosis in 49 presumptive cases [Gauthier] 1181 (Oc)

Neurologic Manifestations
 Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)
 Clinical indicators of intracranial lesion on computed

ed tomographic scan in children with parietal skull fracture [Bonadio] 194 (Fe)

Dexamethasone for children with bacterial meningitis: should it be routine therapy? [Kaplan] (Mr)
 Differential effects of intrauterine and postnatal brain growth failure in infants of very low birth weight [Hack] 63 (Ja)
 Elevated serum levels of tumor necrosis factor associated with progressive encephalopathy in children with acquired immunodeficiency syndrome [Mintz] 771 (Jy)
 Origins of cerebral palsy [Naeye] 1154 (Oc)

Neurology
 Acute remunerative neurology [Ferry] 898 (Au)

Neuropsychological Tests
 Early diagnosis of spastic diplegia, spastic hemiplegia, and quadriplegia [Harris] 1356 (No)

Neurosecretion
 Diagnostic limitations of spontaneous growth hormone measurements in normally growing prepubertal children [Lanes] 1284 (No)

Neutropenia see Agranulocytosis

Neutrophils
Haemophilus influenzae type e (biotype IV) meningitis (letter) [Marshall] 9 (Ja)
 Neonatal neutrophil host defense: prospects for immunologic enhancement during neonatal sepsis [Cairo] 40 (Ja)
 Transient erythroblastopenia of childhood: review of 26 cases and reassessment of indications for bone marrow aspiration [Hays] 605 (My)

New York
 Resident stress (letters) [Giardino, Welliver] 11 (Oc)

New York City
 Acquired immunodeficiency syndrome among adolescents: case surveillance profiles in New York City and rest of United States [Vermund] 1220 (C)
 Health care financing policy for hospitalized pediatric patients [Munoz] 312 (Mr)
 Patient care, resident stress, and government regulation [Cohen] 181 (Fe)
 Queens Boulevard Pedestrian Safety Project
 New York City, leads from *MMWR*, 525 (My)

Night Terrors see Sleep Disorders

Nightmares see Dreams

Nipples see Breast

Nitrogen
 Measured energy expenditure in pediatric intensive care patients [Tilden] 490 (Ap)
 Partition of nitrogen intake and excretion in low birth-weight infants [Donovan] 1485 (De)

Nose
 Regulation of oxygen concentration delivered to infants via nasal cannulas [Vain] 1458 (De)

Nosocomial Infections see Cross Infection

Nutrition Disorders
 Hypophosphatemia in nutritional recovery syndrome [Mezoff] 1111 (Se)
 Low serum complement levels in anorexia nervosa (letter) [Sigal] 1391, (reply) [Eichenfield] 1392 (I)
 Secondary disorders of complement system [Eichenfield] 595 (My)

Nutrition Disorders, Child see Child Nutrition Disorders

O

O'Connor, Mary
 Informed consent and need for delegatization [Woods] 885 (Au)

Obesity
 Effect of weight control on lipid changes in obese children [Epstein] 454 (Ap)

Obstetrics
 Perinatal asphyxia and cerebral palsy: fact, fiction, or legal prediction? [Bedrick] 1139 (Oc)

Occult Blood
 Gastrointestinal milk intolerance of infancy [Bezin] 361 (Mr)

Office Visits
 Model to determine feasibility of pediatric practice [Miller] 919 (Au)
 Pediatric marketplace [Martinez] 924 (Au)

Ohio
 Firearm-associated homicides among family members, relatives or friends—Ohio, leads from *MMWR*, 767 (Jy)

Oklahoma
 Adolescent contraceptive use and parental notification [Demetriou] 1166 (Oc)
 Model to determine feasibility of pediatric practice [Miller] 919 (Au)

Ophthalmoplegia
 Hyperglycemic acidosis with mortality in Kear-Sayre syndrome (letter) [Welch] 1135 (Oc)

Opiates see **Narcotics**

Opportunistic Infections
Natural history and serologic diagnosis of infants born to human immunodeficiency virus-infected women [Johnson] 1147 (Oc)

Optic Nerve Diseases
Puberty in syndrome of septo-optic dysplasia [Hanna] 186 (Fe)

Orciprenaline
Use of adrenergic bronchodilators by pediatric allergists and pulmonologists [Newcomb] 481 (Ap)

Organophosphorus Compounds
Serum phosphate concentration: effect on serum ionized calcium concentration in vitro [Lehmann] 1340 (No)

Orthomyxoviruses Type A
Influenza vaccine composition recommendation for 1989-90 season, leads from *MMWR*, 768 (Jy)

Orthomyxoviruses Type B
Influenza vaccine composition recommendation for 1989-90 season, leads from *MMWR*, 768 (Jy)

Oscillometry
Normative oscillometric blood pressure values in first five years in office setting [Park] 860 (Jy)

Osteoarthropathy, Secondary Hypertrophic
Hypertrophic pulmonary osteoarthropathy [Bokulich] 747 (Je)

Osteoma, Osteoid
Computed tomography in diagnosis of osteoid osteoma in infancy (letter) [Fleta] 1000 (Se)

Osteonecrosis
Osteonecrosis of femoral head diagnosed by magnetic resonance imaging [Barzel] 623 (My)

Osteopenia see **Bone Diseases, Metabolic**

Osteotomy
State-of-the-art reconstructive surgery for bladder exstrophy at Johns Hopkins Hospital [Gearhart] 1475 (De)

OTC Drugs see Drugs, Non-Prescription

Otitis Media
Are 'hot' ears really hot? (letter) [Weir] 763 (Jy)
Prophylaxis of recurrent acute otitis media and middle-ear effusion: comparison of amoxicillin with sulfamethoxazole and trimethoprim [Principi] 1414 (De)

Otitis Media with Effusion
Otolgic manifestations in congenital velopharyngeal insufficiency [Durr] 75 (Ja)
Prophylaxis of recurrent acute otitis media and middle-ear effusion: comparison of amoxicillin with sulfamethoxazole and trimethoprim [Principi] 1414 (De)

Outpatient Clinics, Hospital
Computerized patient scheduling in outpatient residency practices [Quattlebaum] 1333 (No)
Does residents' continuity clinic provide primary care? [Wilson] 809 (Jy)
Long-term outcome of adolescents with anorexia nervosa [Kreipe] 1322 (No)

Over-the-Counter Drugs see **Drugs, Non-Prescription**

Overutilization of Health Services see **Health Services**

Oximetry
Failure of electrocardiographic monitoring to detect cardiac arrest in patients with pacemakers [Brownlee] 105 (Ja)
Pulse oximetry in methemoglobinemia [Watcha] 845 (Jy)

Oxygen
Increased phagocytic cell chemiluminescence in patients with cystic fibrosis [Roberts] 944 (Au)
Neonatal hyperbilirubinemia at high altitude [Leibson] 983 (Au)
Pulse oximetry in methemoglobinemia [Watcha] 845 (Jy)

Oxygen Consumption
Predicting maximum oxygen uptake in adolescents [Hergenroeder] 673 (Je)
Regulation of oxygen concentration delivered to infants via nasal cannulas [Vain] 1458 (De)

Oxygen Inhalation Therapy
Home oxygen therapy for chronic lung disease in extremely low-birth-weight infants [Hudak] 357 (Mr)

Treatment of croup: critical review [Skolnik] 1045 (Se)

Oxygen Partial Pressure Determination, Transcutaneous see **Blood Gas Monitoring, Transcutaneous**

Oxyhemoglobins
Pulse oximetry in methemoglobinemia [Watcha] 845 (Jy)

Oxytocin
Origins of cerebral palsy [Naeye] 1154 (Oc)

P

Pacemaker, Artificial
Failure of electrocardiographic monitoring to detect cardiac arrest in patients with pacemakers [Brownlee] 105 (Ja)

Palatopharyngeal Incompetence see **Velopharyngeal Insufficiency**

Pamphlets
Educational booklet diminishes anxiety in parents whose children receive total parenteral nutrition [Laine] 374 (Mr)

Pancreas
Effect of pancreatic enzyme supplements on iron absorption [Zemsky] 969 (Au)

Pancreatic Function Tests
Hyperglycemic acidosis with mortality in Kearns-Sayre syndrome (letter) [Welch] 1135 (Oc)

Pancreatitis
Secondary disorders of complement system [Eichenfield] 595 (My)

Papillomaviruses
Antiviral drugs in pediatrics [Balfour] 1307 (No)
High prevalence rate of human papillomavirus infection and association with positive Papanicolaou smears in sexually active adolescents [Rosenfeld] 1443 (De)

Paralysis
Poliovirus vaccine policy: another perspective [Katz] 1007 (Se)
Why wait for DTP-E-IPV? [Marcuse] 1006 (Se)

Parent-Child Relations
Adolescent contraceptive use and parental notification [Demetriou] 1166 (Oc)

Parenteral Hyperalimentation
Educational booklet diminishes anxiety in parents whose children receive total parenteral nutrition [Laine] 374 (Mr)

Parents
Advising parents to stop smoking: opportunities and barriers in pediatric practice [Frankowski] 1091 (Se)
Age-related patterns of violent death, Cook County, Illinois, 1977 through 1982 [Christoffel] 1403 (De)
Circumstances surrounding deaths of children due to asthma: case control study [Miller] 1294 (No)
Educational booklet diminishes anxiety in parents whose children receive total parenteral nutrition [Laine] 374 (Mr)
House call—is it an anachronism that has seen its day? [Blumberg] 1281 (No)
Impact of fever health education on clinic utilization [Robinson] 668 (Je)
Importance of parents' concerns about their child's development [Glascoe] 955 (Au)
Informed consent for lumbar puncture [Botkin] 899 (Au)
Parent, teacher, child: trilateral approach to attention deficit disorder [Cohen] 1229 (Oc)
Polymicrobial bacteremia and child abuse (letter) [Amir] 444 (Ap)
Thank you Robin and Richard [Pruitt] 534 (My)
You are a preventive cardiologist: scope of pediatric preventive cardiology [Strong] 1145 (Oc)

Parietal Bone
Clinical indicators of intracranial lesion on computed tomographic scan in children with parietal skull fracture [Bonadio] 194 (Fe)

Partial Pressure
High-frequency jet ventilation in neonatal pulmonary hypertension [Carlo] 233 (Fe)
Pulse oximetry in methemoglobinemia [Watcha] 845 (Jy)

Patient Appointments see **Appointments and Schedules**

Patient Care Team
Computers in medicine: augmenting medical care in pediatric patients with chronic illnesses [Handler] 1021 (Se)
Management of diabetes in pediatric resident continuity clinics [Kronz] 1173 (Oc)

Patient Compliance
Age, gender, and metabolic control in children and adolescents with diabetes (letter) [Zimet] 1134 (Oc)
Psychosocial determinants of compliance in adolescents with iron deficiency [Cromer] 55 (Ja)

Patient Discharge
Safety of newborn discharge in less than 36 hours in indigent population [Conrad] 98 (Ja)
Updating immunization status at discharge (letter) 879 [Walterspiel] (Au)

Patient Education
Age, gender, and metabolic control in children and adolescents with diabetes (letter) [Zimet] 1134 (Oc)
Breast-feeding pattern among Indo-Chinese immigrants in northern California [Romero-Gwynn] 864 (Jy)

Educational booklet diminishes anxiety in parents whose children receive total parenteral nutrition [Laine] 374 (Mr)

Patient Readmission
Safety of newborn discharge in less than 36 hours in indigent population [Conrad] 98 (Ja)

Patient Satisfaction see **Consumer Satisfaction**

Patients
Thank you Robin and Richard [Pruitt] 534 (My)

Peak Expiratory Flow Rate see **Forced Expiratory Flow Rates**

Peanuts
Tracheobronchial foreign bodies: persistent problem in pediatric patients [Puhakka] 543 (My)

PEDIATRIC PERSPECTIVES
Beware of overtreating children! [Cunningham] 786 (Jy)
International adoption: introduction for physicians [Hostetter] 325 (Mr)
Patient care, resident stress, and government regulation [Cohen] 181 (Fe)
Pediatrician as consultant [Stickler] 73 (Ja)
Stress experienced during pediatric residency training: its causes, consequences, recognition, and solutions [Hoekelman] 177 (Fe)

Pediatrics
Advising parents to stop smoking: opportunities and barriers in pediatric practice [Frankowski] 1091 (Se)
Antiviral drugs in pediatrics [Balfour] 1307 (No)
Attitudes toward mental illness prevention in routine pediatric practice [Yager] 1089 (Se)
Beware of overtreating children! [Cunningham] 786 (Jy)
Cleveland, England: child abuse in public eye [Fulginiti] 651 (Je)
Comment on 'pediatrician as consultant' (letter) [Levenson] 641, (reply) [Stickler] 642 (Je)
Computers in medicine: augmenting medical care in pediatric patients with chronic illnesses [Handler] 1021 (Se)
Documentation of students' clinical reasoning using computer simulation [Schwartz] (editorial comment) [Allen] 575 (My)
Does residents' continuity clinic provide primary care? [Wilson] 809 (Jy)
George Armstrong (1719-1787): founder of first dispensary for children [Bloch] 239 (Fe)
Growth retardation: impaired height velocity [Penny] 1269 (No)
Head injury training for pediatric residents [Tyler] 930 (Au)
Is standard practice in pediatrics 'standard'? potential lesson for experts and practitioners [Fulginiti] 529 (My)
Lead screening at pediatric teaching programs [Edwards] 1455 (De)
Management of diabetes in pediatric resident continuity clinics [Kronz] 1173 (Oc)
Model to determine feasibility of pediatric practice [Miller] 919 (Au)
Nightmares on Main Street [Schmitt] 649 (Je)
Normative oscillometric blood pressure values in first 5 years in office setting [Park] 860 (Jy)
1-month elective in international health for senior pediatric residents (letter) [Duncan] 1389 (De)
Patient care, resident stress, and government regulation [Cohen] 181 (Fe)
Pediatric biographies: George Armstrong (1930) [Ruhrah] 242; commentary [Fulginiti] 244 (Fe)
Pediatric marketplace [Martinez] 924 (Au)
Pediatrician as consultant [Stickler] 73 (Ja)
Pediatrician as mother (letter) [Furman] 638 (Je)
Pediatricians' recommendations for antipyretic agents with DTP immunizations: survey of current practice (letter) [Flanagan] 517 (My)
Perinatal asphyxia and cerebral palsy: fact, fiction, or legal prediction? [Bedrick] 1139 (Oc)
PhD faculty in clinical department (letter) [Gormley] 11 (Ja)
Prescription of psychotropics to children in office-based practice [Kelleher] 855 (Jy)
Pyomyositis in child with acquired immunodeficiency syndrome: patient report and brief review [Raphael] 779 (Jy)
Research during residency (letter) [Winter] 521 (My)
Residency training in general pediatrics: career direction of primary care graduates [Mathieu] 217 (Fe)
Resident stress (letters) [Giardino, Welliver] 1129 (Oc)
Smoking policy in pediatric hospitals and wards [Jenista] 567 (My)
Stress experienced during pediatric residency training program (letter) [Schubert] 1257 (No)
Stress experienced during pediatric residency training: its causes, consequences, recognition,

and solutions [Hoekelman] 177 (Fe)
 Survey of severe eye injuries in children [DeRespinis] 711 (Je)
 Thank you Robin and Richard [Pruitt] 534 (My)
 Thoughts on residency education, 1969-1989 [Roberts] 294 (Mr)
 Use of adrenergic bronchodilators by pediatric allergists and pulmonologists [Newcomb] 481 (Ap)
 Why are there no educators with PhD degrees in pediatric departments? (letter) [Greenberg] 10 (Ja)
 You are a preventive cardiologist: scope of pediatric preventive cardiology [Strong] 1145 (Oc)
Peer Group
 Barriers to bicycle helmet use among children: results of focus groups with fourth, fifth, and sixth graders [Howland] 741 (Je)
Penicillin V see Penicillin, Phenoxymethyl Penicillin, Phenoxymethyl
 Twice-daily therapy for strep? (letter) [Gill] (reply) [Gerber] 997 (Se)
Penicillins
 Clinical and bacteriologic features of chronic sinusitis in children [Tinkelman] 938 (Au)
 Failure of once-daily penicillin V therapy for streptococcal pharyngitis [Gerber] 153 (Fe)
Penis
 State-of-the-art reconstructive surgery for bladder exstrophy at Johns Hopkins Hospital [Gearhart] 1475 (De)
Peptic Ulcer
Campylobacter pylori gastritis and peptic ulcer in children (letters) [Oderda, Chiesa] 877, (reply) [Dahms] 878 (Au)
Perceptual Disorders
 Neurologic status and intracranial hemorrhage in very low-birth-weight preterm infants: outcome at 1 year and 5 years [Ford] 1186 (Oc)
Perceptual Motor Performance see Psychomotor Performance

Clinical identification and comparative prognosis of high-risk patients with *Haemophilus influenzae* meningitis [Gary] 307 (Mr)

Clinical predictors of *Chlamydia trachomatis* endocervicitis in adolescent women: looking for right combination [Remafedi] 1437 (De)

Differential effects of intrauterine and postnatal brain growth failure in infants of very low birth weight [Hack] 63 (Ja)

Does maternal smoking during pregnancy cause cleft lip and palate in offspring? [Khouri] 333 (Mr)

Epidemiology of cluster of Henoch-Schönlein purpura [Farley] 798 (Jy)

Firearm-associated homicides among family members, relatives or friends—Ohio, leads from *MMWR*, 767 (Jy)

High prevalence rate of human papillomavirus infection and association with positive Papanicolaou smears in sexually active adolescents [Rosenfeld] 1443 (De)

Hypophosphatemia in nutritional recovery syndrome [Mezoff] 1111 (Se)

Klebsiella pneumoniae bacteremia in children: 57 cases in 10 years [Bonadio] 1061 (Se)

Late sudden unexpected deaths in hospitalized infants with bronchopulmonary dysplasia [Abman] 815 (Jy)

Origins of cerebral palsy [Naeye] 1154 (Oc)

Postdelivery head bleeding in hemophilic neonates: causes and management [Kietzel] 1107 (Se)

Recurrent injuries in schoolchildren [Boyce] 338 (Mr)

Respiratory syncytial virus outbreak on American Samoa: evaluation of risk factors [Hayes] 316 (Mr)

Risk factors for infant botulism in United States [Spika] 828 (Jy)

TEARS: does domestic violence play role? (letter) [Rimsza] 137 (Fe)

Unintentional injuries: risk factors in preschool children [Bourguet] 556 (My)

Urinary tract infections and circumcision: case-control study [Herzog] 348 (Mr)

Risk-Taking

What causes sexual assault? (letter) [Margolis] (reply) [Jenny] 137 (Fe)

Roentgenography see Radiography

Role

Adolescent health: synopsis of conference [Brown] 466 (Ap)

DICE: nonclinical causes of overtreatment (letter) [Cunningham] 142 (Fe)

Role Concept see Role

Rubella

Neurological and developmental findings in children with cataracts [Pike] 706 (Je)

Rubella and congenital rubella syndrome—United States, 1985-1988, leads from *MMWR*, 893 (Au)

Rubella Syndrome, Congenital see Rubella

Rural Health

Risk factors for infant botulism in United States [Spika] 828 (Jy)

Rural Population

Firearm ownership among nonurban adolescents [Sadowski] 1410 (De)

S

Safety Devices see Protective Devices

Salicylates

Hidden salicylates (letter) [Szap] 142 (Fe)

Saudi Arabia

Infections and sickle cell disease in eastern Saudi

Arabian children [Mouzan] 205 (Fe)

Scalp

Cutis verticis gyrata and chromosomal abnormalities (letter) [Marini] 269 (Mr); correction, 592 (My)

Scars see Cicatrix

Schools

Barriers to bicycle helmet use among children: results of focus groups with fourth, fifth, and sixth graders [Howland] 741 (Je)

Epidemic hysteria dilemma (letter) [Cartter] 269 (Mr)

Publication of guide for developing policies for HIV-infected students and school staff, leads from *MMWR*, 1397 (De)

Recurrent injuries in schoolchildren [Boyce] 338 (Mr)

School breakfast program and school performance [Meyers] 1234 (Oc)

Transmission of chickenpox in school setting prior to observed exanthem [Brunell] 1451 (De)

Schools, Medical

Education about adult domestic violence in U.S. and Canadian medical schools, 1987-88, leads from *MMWR*, 447 (Ap)

Scleridiae

Human plague—United States, 1988, leads from *MMWR*, 145 (Fe)

Scleroderma, Circumscribed

Morphea [Iyer] 1353 (No)

Seat Belts

Falls from pickup trucks during childhood (letter) [Tong] 997 (Se)

Injuries among 4- to 9-year old restrained motor vehicle occupants by seat location and crash impact site [Agran] 1317 (No)

Jejunal stenosis: delayed complication of lap-type seat belt injury (letter) [Weinberg] 1392 (De)

Secretary Rate

Criteria for recognition of growth-inefficient child who may respond to treatment with growth hormone [Saggese] 1287 (No)

Diagnostic limitations of spontaneous growth hormone measurements in normally growing prepubertal children [Lanes] 1234 (No)

Seeds

Sunflower seed bezoar presenting as diarrhea (letter) [Dent] 643 (Je)

Seizures

Low-dose alternate-day corticotropin therapy in treatment of childhood seizures (letter) [Dooley] 1263 (No)

Methylphenidate in children with seizures and attention-deficit disorder [Feldman] 1081 (Se)

Passive freebase cocaine ("crack") inhalation by infants and toddlers [Bateman] 25 (Ja)

Seizures, Febrile see Convulsions, Febrile

Self Care

Health status of children in self-care [Williams] 112 (Ja)

Self Concept

Adolescence: what is normal? [Offer] 731 (Je)

Psychosocial determinants of compliance in adolescents with iron deficiency [Cromer] 55 (Ja)

Reported sexual behaviors and self-esteem among young adolescents [Orr] 86 (Ja)

Self Esteem see Self Concept

Sella Turcica

Perinatal abnormalities and subhypothalamic bright spot on magnetic resonance imaging in pituitary dwarfs (letter) [Okabe] 1394 (De)

Septicemia

Klebsiella pneumoniae bacteremia in children: 57 cases in 10 years [Bonadio] 1061 (Se)

Occult bacteremia in children with simple febrile seizures (letters) [Torphy, Bonadio] 273, (reply) [Chamberlain] 274 (Mr)

Polymicrobial bacteremia and child abuse (letter) [Amir] 444 (Ap)

Risk of infectious complications in well-appearing children with transient neutropenia [Alario] 973 (Au)

Septum Pellucidum

Puberty in syndrome of septo-optic dysplasia [Hann] 186 (Fe)

Serodiagnosis

Clear heads and Bayesian tales: predictive value and coin toss? (letter) [Mauro] 1000 (replies) [Halperin, Brown] 1001 (Se)

Toxoplasmosis needs evaluation: overview and proposals [Koskiniemi] 724 (Je)

Serology

Interactions of alcohol and nutrition (letter) [da Cunha Ferreira] 519 (My); correction, 1110 (Se)

Non-group A streptococci in pharynx: pathogens or innocent bystanders? [Hayden] 794 (Jy)

Prevalence of drug use among applicants for military service—United States, June-December

1988, leads from *MMWR*, 1273 (No)

Severity of Illness Index

Pediatric patients, race, and DRG prospective hospital payment [Munoz] 612 (My)

Sex Behavior

Acquired immunodeficiency syndrome among adolescents: case surveillance profiles in New York City and rest of United States [Vermund] 1220 (Oc)

Adolescent contraceptive use and parental notification [Demetriou] 1166 (Oc)

Adolescent heterosexual relationship and its association with sexual and contraceptive behavior of black girls [DuRant] 1467 (De)

Clinical predictors of *Chlamydia trachomatis* endocervicitis in adolescent women: looking for right combination [Remafedi] 1437 (De)

High prevalence rate of human papillomavirus infection and association with positive Papanicolaou smears in sexually active adolescents [Rosenfeld] 1443 (De)

HIV-related beliefs, knowledge, and behaviors among high school students, leads from *MMWR*, 145 (Fe)

Reported sexual behaviors and self-esteem among young adolescents [Orr] 86 (Ja)

Sex Education

Adolescents and condoms: associations of beliefs with intentions to use [Kegeles] 911 (Au)

Sex Factors

Age, gender, and metabolic control in children and adolescents with diabetes (letter) [Zimet] 1134 (Oc)

Bone mineral content in black and white children 1 to 6 years of age: early appearance of race and sex differences [Li] 1346 (No)

Congenital cardiovascular malformations in twins and triplets from population-based study [Berg] 1461 (De)

Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Jy)

Firearm ownership among nonurban adolescents [Sadowski] 1410 (De)

High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)

Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)

Recurrent injuries in schoolchildren [Boyce] 338 (Mr)

Survey of severe eye injuries in children [DeRespinis] 711 (Je)

Sex Offenses

What causes sexual assault? (letter) [Margolis] (reply) [Jenny] 137 (Fe)

Sexually Transmitted Diseases

Adolescents and condoms: associations of beliefs with intentions to use [Kegeles] 911 (Au)

High prevalence rate of human papillomavirus infection and association with positive Papanicolaou smears in sexually active adolescents [Rosenfeld] 1443 (De)

Pregnant adolescent prostitute [Deisher] 1162 (Oc)

Reported sexual behaviors and self-esteem among young adolescents [Orr] 86 (Ja)

Sexually transmitted diseases curriculum in adolescent medicine [Johnson] 1073 (Se)

Sexually Transmitted Diseases, Bacterial

Gonococcal conjunctivitis mimicking orbital cellulitis in young adolescent (letter) [Legido] 443 (Ap)

Shock, Septic

Toxic shock syndrome caused by strain of *Staphylococcus aureus* that produces enterotoxin C but not toxic shock syndrome toxin-1 [Rizkallah] 848 (Jy)

Sibling Relations

Evaluation of camp program for siblings of children with cancer [Sahler] 690 (Je)

Sickle Cell Trait see Anemia, Sickle Cell

SID see Sudden Infant Death

Silicone Elastomers

Prolonged intravenous infusions (letter) [Sussman] 520, (reply) [Shulman] 521 (My)

Sinusitis

Chronic sinusitis: disease of all ages [Rachelefsky] 886 (Au)

Clinical and bacteriologic features of chronic sinusitis in children [Tinkelman] 938 (Au)

Nasal septal abscess; inflammatory nasal polyps; intranasal glioma [Wiatrak] 501 (Ap)

Skin

Congenital rhabdomyomatous mesenchymal hamartoma of skin [Levkoff] 963 (Au)

Small, single-vertex lesion of scalp aplasia cutis congenita; *Trichophyton tonsurans*; aplasia cutis congenita [Cohen] 621 (My)

Skin Absorption

Adhesive tape remover pads: risk to newborn? (letter) [Lacouture] 1391 (De)

Skull Fractures

Clinical indicators of intracranial lesion on computed tomographic scan in children with parietal skull fracture [Bonadio] 194 (Fe)

Sleep

Circumstances surrounding deaths of children due to asthma: case control study [Miller] 1294 (No)

Infant sleep and bedtime cereal [Mackinn] 1066 (Se)

Sleep Disorders

Nightmares on Main Street [Schmitt] 649 (Je)

Smoking

Advising parents to stop smoking: opportunities and barriers in pediatric practice [Frankowski] 1091 (Se)

Does maternal smoking during pregnancy cause cleft lip and palate in offspring? [Khouri] 333 (Mr)

Respiratory syncytial virus outbreak on American Samoa: evaluation of risk factors [Hayes] 316 (Mr)

Smoking policy in pediatric hospitals and wards [Jenista] 567 (My)

Smoking, Passive see Tobacco Smoke Pollution

Social Change

Being just a husband is no fun [Stiehm] 1401 (De)

Social Environment

Adolescent health: synopsis of conference [Brown] 466 (Ap)

Adolescent heterosexual relationship and its association with sexual and contraceptive behavior of black girls [DuRant] 1467 (De)

Connectedness [McAnarney] 453 (Ap)

Pregnant adolescent prostitute [Deisher] 1162 (Oc)

Psychosocial determinants of compliance in adolescents with iron deficiency [Cromer] 55 (Ja)

Social Responsibility

Adolescent health: synopsis of conference [Brown] 466 (Ap)

Social Support see Social Environment

Society for Pediatric Research

1989 annual meeting, May 1-4, 1989, Washington D.C., program, 410-411; abstracts 429-438 (Ap)

Socioeconomic Factors

Determinants of school performance in children with chronic asthma [Gutstadt] 471 (Ap)

Epidemiology of cluster of Henoch-Schönlein purpura [Farley] 798 (Jy)

Firearm ownership among nonurban adolescents [Sadowski] 1410 (De)

Pediatric patients, race, and DRG prospective hospital payment [Munoz] 612 (My)

Psychosocial determinants of compliance in adolescents with iron deficiency [Cromer] 55 (Ja)

School breakfast program and school performance [Meyers] 1234 (Oc)

TEARS: does domestic violence play role? (letter) [Rimsza] 137 (Fe)

Sodium

On combination therapy with benzoate and piridoxilate (letter) [Cyr] 1392 (De)

Software

Computers in medicine: augmenting medical care in pediatric patients with chronic illnesses [Handler] 1021 (Se)

Somatomedins

Criteria for recognition of growth-inefficient child who may respond to treatment with growth hormone [Saggese] 1287 (No)

Diagnostic limitations of spontaneous growth hormone measurements in normally growing prepubertal children [Lanes] 1284 (No)

Insulinlike growth factors in patients with active nephrotic syndrome [Garin] 865 (Jy)

Somatotropin

Criteria for recognition of growth-inefficient child who may respond to treatment with growth hormone [Saggese] 1287 (No)

Diagnostic limitations of spontaneous growth hormone measurements in normally growing prepubertal children [Lanes] 1284 (No)

Diagnostic value of testosterone therapy in boys with delayed puberty [Kaplowitz] 116 (Ja)

Growth hormone treatment in children with sporadic primary microcephaly [Spadoni] 1282 (No)

Growth response of growth hormone-deficient patients to 0.06 mg/kg compared with 0.10 mg/kg 3 times per week of biosynthetic growth hormone (letter) [Rosenbloom] 642 (Je)

Growth retardation: impaired height velocity [Penney] 1269 (No)

Puberty in syndrome of septo-optic dysplasia [Hanna] 186 (Fe)

South Carolina

Scombroid fish poisoning—Illinois, South Carolina, leads from *MMWR*, 646 (Je)

Soybeans

Gastrointestinal milk intolerance of infancy [Berezin] 361 (Mr)

Space-Time Clustering

Epidemiology of cluster of Henoch-Schönlein purpura [Farley] 798 (Jy)

Spasms, Infantile

Low-dose alternate-day corticotropin therapy in treatment of childhood seizures (letter) [Dooley] 1263 (No)

Specialties, Medical

Pediatrician as consultant [Stickler] 73 (Ja)

Stress experienced during pediatric residency training program (letter) [Schubert] 1257 (No)

Spectrophotometry

Capillary and venous bilirubin values: they are different—and how! (letter) [Eidelman] 642 (Je)

Spermatogenesis

Onset of sperm production in pubertal boys: relationship to gonadotropin excretion [Kuhin] 190 (Fe)

Spider Bite see Arachnidism

Spiders

Loxosceles reclusa; bite of brown recluse spider; typical bite of brown recluse spider with local cyanotic pustule and necrosis [Demmler] 843 (Jy)

Spinal Puncture

Ameliorating effect of lumbar puncture in viral meningitis [Jaffe] 682 (Je)

Informed consent for lumbar puncture [Botkin] 899 (Au)

Neonatal *Staphylococcus epidermidis* meningitis with unremarkable CSF examination results [Gruskay] 580 (My)

Sports

Barriers to bicycle helmet use among children: results of focus groups with fourth, fifth, and sixth graders [Howland] 741 (Je)

High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)

Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)

Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)

SPORTS MEDICINE

High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)

Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)

Predicting maximum oxygen uptake in adolescents [Hergenroeder] 673 (Je)

Strength, flexibility, and maturity in adolescent athletes [Pratt] (editorial comment) [Strong] 560 (My)

Squirrel sees Scluridae

Staphylococcus aureus

Anti-*Staphylococcus aureus* IgE antibodies for diagnosis of hyperimmunoglobulinemia E-recurrent infection syndrome in infancy [Lavioie] 1038 (Se)

Comparison of amoxicillin and clavulanic acid (Augmentin) for treatment of nonbullous impetigo [Dagan] 916 (Au)

Effect of respiratory viral infections on patients with cystic fibrosis [Ramsey] 662 (Je)

Epidemic methicillin-gentamicin-resistant *Staphylococcus aureus* in neonatal intensive care unit [Reboli] 34 (Ja)

Extrapleural effusion of retropharyngeal origin [Martinot] 1207 (Oc)

Morbidity and mortality in children with pyogenic liver abscess [Pineiro-Carrero] 1424 (De)

Pyomyositis in child with acquired immunodeficiency syndrome: patient report and brief review [Raphael] 779 (Jy)

Toxic shock syndrome caused by strain of *Staphylococcus aureus* that produces enterotoxin C but not toxic shock syndrome toxin-1 [Rizkallah] 848 (Jy)

Staphylococcus epidermidis

Neonatal *Staphylococcus epidermidis* meningitis with unremarkable CSF examination results [Gruskay] 580 (My)

State Government see Government

Statistics

Assessment of neurodevelopmental outcome in surfactant-replacement therapy (letter) [Langkamp] 762, (reply) [Vaucher] 763 (Jy)

Praise for useful words [Brown] 770 (Jy)

Reconsideration of IgM-enriched intravenous immunoglobulin for neonatal sepsis (letter) [Hall] (reply) [Haque] 766 (Jy)

Steatorrhea see Celiac Disease

Steroids

Circumstances surrounding deaths of children due to asthma: case control study [Miller] 1294 (No)

Osteonecrosis of femoral head diagnosed by magnetic resonance imaging [Barzel] 623 (My)

Puberty in syndrome of septo-optic dysplasia [Hanna] 186 (Fe)

Sex steroids do not influence somatic growth in

emmanoud [Campos] 942 (Au)

Stimulation, Chemical

Increased phagocytic cell chemiluminescence in patients with cystic fibrosis [Roberts] 944 (Au)

Stomach Volvulus

Intrathoracic stomach with volvulus [Bonadio] 194 (Fe)

Streptococcal Infections

Comparison of amoxicillin and clavulanic acid (Augmentin) for treatment of nonbullous impetigo [Dagan] 916 (Au)

Diagnosis of group A, beta-hemolytic streptococcal pharyngitis in office setting: rapid latex test throat culture [Taubman] 102 (Ja)

Twice-daily therapy for strep? (letter) [Gill] (reply) [Gerber] 997 (Se)

Streptococcus

Emergence of isolates resistant to ampicillin [Lipman] 1033 (Se)

Non-group A streptococci in pharynx: pathogen or innocent bystanders? [Hayden] 794 (Jy)

Streptococcus agalactiae

Prostaglandin E₂ selectively reduces group B beta-hemolytic streptococci-induced pulmonary hypertension in newborn piglets [Hammerman] 343 (Oc)

Use of intravenous immunoglobulin in treatment of neonatal sepsis [letter] [Kim] 1257 (No)

Streptococcus faecalis

Emergence of isolates resistant to ampicillin [Lipman] 1033 (Se)

Streptococcus Group A see Streptococcus pyogenes

Streptococcus Group B see Streptococcus agalactiae

Streptococcus pneumoniae

Clinical and bacteriologic features of chronic sinusitis in children [Tinkelman] 938 (Au)

Occult bacteremia in children with simple febrile seizures (letters) [Torphy, Bonadio] 273, (reply) [Chamberlain] 274 (Mr)

Septic arthritis in children with hemophilia [Papadimitrakou] 1226 (Oc)

Streptococcus pyogenes

Diagnosis of group A, beta-hemolytic streptococcal pharyngitis in office setting: rapid latex test throat culture [Taubman] 102 (Ja)

Diagnosis of group A, beta-hemolytic streptococcal pharyngitis in office setting (letter) [Kellogg] (reply) [Taubman] 761 (Jy)

Epidemiology of cluster of Henoch-Schönlein purpura [Farley] 798 (Jy)

Failure of once-daily penicillin V therapy for streptococcal pharyngitis [Gerber] 153 (Fe)

Twice-daily therapy for strep? (letter) [Gill] (reply) [Gerber] 997 (Se)

Streptomycin

Emergence of isolates resistant to ampicillin [Lipman] 1033 (Se)

Stress

Circumstances surrounding deaths of children due to asthma: case control study [Miller] 1294 (No)

Patient care, resident stress, and government regulation [Cohen] 181 (Fe)

Resident stress (letters) [Giardino, Welliver] 1033 (Oc)

Stress experienced during pediatric residence training: its causes, consequences, recognition and solutions [Hoekelman] 177 (Fe)

Stress experienced during pediatric residence training program (letter) [Schubert] 1257 (No)

Students

Epidemic hysteria dilemma (letter) [Cartter] 1033 (Mr)

High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)

Publication of guide for developing policies for HIV-infected students and school staff, leads from *MMWR*, 1397 (De)

School breakfast program and school performance [Meyers] 1234 (Oc)

Transmission of chickenpox in school setting ppe to observed exanthem [Brunell] 1451 (De)

Students, Medical

Documentation of students' clinical reasoning using computer simulation [Schwartz] (editorial comment) [Allen] 575 (My)

Subcutaneous Emphysema see Emphysema

Substance Abuse

Acquired immunodeficiency syndrome among adolescents: case surveillance profiles in New York City and rest of United States [Vermund] 1220 (Oc)

Drug usage among adolescents: survey from pediatric/adolescent practice (letter) [Buchta] 765 (Fe)

First 100,000 cases of acquired immunodeficiency syndrome—United States, leads from *MMWR*, 1274 (No)

High school athletes and use of ergogenic aids [Krowchuk] 486 (Ap)

HIV-related beliefs, knowledge, and behaviors among high school students, leads from *MMWR*, 145 (Fe)

Passive freebase cocaine ('crack') inhalation by infants and toddlers [Bateman] 25 (Ja)

Passive inhalation of marijuana, phencyclidine, and freebase cocaine ('crack') by infants (letter) [Schwartz] 644 (Je)

Perinatal outcome of infants exposed to cocaine and/or heroin in utero [Fulroth] 905 (Au)

Pregnant adolescent prostitute [Deisher] 1162 (Oc)

Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (My)

Prevalence of drug use among applicants for military service—United States, June-December 1988, leads from *MMWR*, 1273 (No)

Unintentional poisoning mortality—United States, 1980-1986, leads from *MMWR*, 645 (Je)

Urine drug screening in mothers and newborns [Osterloh] 791 (Jy)

Substance Withdrawal, Neonatal see **Neonatal Abstinence Syndrome**

Suburban Population

Firearm ownership among nonurban adolescents [Sadowski] 1410 (De)

Sucking Behavior

Sucking and breathing patterns during breast- and bottle-feeding in term neonates: effects of nutrient delivery and composition [Mathew] 588 (My)

Sudden Infant Death

Gastroesophageal reflux-induced hypoxemia in infants with apparent life-threatening event(s) [See] 951 (Au)

Late sudden unexpected deaths in hospitalized infants with bronchopulmonary dysplasia [Abman] 815 (Jy)

Neonatal intensive care: at what price? [Bedrick] 451 (Ap)

Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (My)

Sudden infant death syndrome as cause of premature mortality—United States, 1984 and 1985, leads from *MMWR*, 126 (Ja)

Sulfamethoxazole

Cat-scratch disease therapy (letter) [Collipp] 1261 (No)

Clinical and bacteriologic features of chronic sinusitis in children [Tinkelman] 938 (Au)

Prophylaxis of recurrent acute otitis media and middle-ear effusion: comparison of amoxicillin with sulfamethoxazole and trimethoprim [Principi] 1414 (De)

Sulfates

Protein intake and renal function in children [Nakano] 160 (Fe)

Sunflower see **Helianthus**

Suppuration

Acute suppurative adenoiditis (letter) [Weir] 998 (Se)

Morbidity and mortality in children with pyogenic liver abscess [Pineiro-Carrero] 1424 (De)

Surface-Active Agents

Assessment of neurodevelopmental outcome in surfactant-replacement therapy (letter) [Langkamp] 762, (reply) [Vaucher] 763 (Jy)

Surfactants see **Surface-Active Agents**

Surgery, Operative

Cholecystectomy in sickle cell anemia (letter) [Gerry] 764 (Jy)

Clinical and bacteriologic features of chronic sinusitis in children [Tinkelman] 938 (Au)

Correction of atrioventricular septal defect [Vet] 1861 (No)

Fetal surgery in 1990s [Evans] 1431 (De)

Patterns of cardiac care in infants with Down syndrome [Schneider] 363 (Mr)

Plasma support for surgery in premature infant with factor IX deficiency (letter) [Pegelow] 639 (Je)

Surgery, Plastic

State-of-the-art reconstructive surgery for bladder exstrophy at Johns Hopkins Hospital [Gearhart] 1475 (De)

Sweetening Agents

Risk factors for infant botulism in United States [Spika] 828 (Jy)

Swimming

Iron deficiency in athletes: insights from high school swimmers [Rowland] 197 (Fe)

Swimming Pools

Injury prevention: drowning (letter) [Smith] (reply) [Noyes] 272 (Mr)

Swine

Prostaglandin E, selectively reduces group B beta-hemolytic streptococci-induced pulmonary hypertension in newborn piglets [Hammerman] 343 (Mr)

Symphactomy, Chemical

Hirschsprung's disease and ocular autonomic nerve

function (letter) [O'Connor] 1137 (Oc)

Systole see **Myocardial Contraction**

T

Teaching

Parent, teacher, child: trilateral approach to attention deficit disorder [Cohen] 1229 (Oc)

Technology, Medical

Advances in neonatal care (letter) [Goetzman] 441 (Ap)

Beware of overtreating children! [Cunningham] 786 (Jy)

Neonatal intensive care: at what price? [Bedrick] 451 (Ap)

Telangiectasis

Reticulated pattern of telangiectasias on infant arm; urticaria pigmentosa; hyperpigmentation; incontinentia pigmenti [Cohen] 255 (Fe)

Telephone

Telephone etiquette: telephone, one of physician's most necessary and, at times, most hated devices (letter) [Stickler] 520 (My)

Television

Nightmares on Main Street [Schmitt] 649 (Je)

Temporal Bone

Monostotic fibrous dysplasia of temporal bone [Talmi] 1351 (No)

Teratogens

Complex congenital heart disease after in vitro fertilization (letter) [Marino] 1136 (Oc)

Does maternal smoking during pregnancy cause cleft lip and palate in offspring? [Khouri] 333 (Mr)

Terbutaline

Use of adrenergic bronchodilators by pediatric allergists and pulmonologists [Newcomb] 481 (Ap)

Testis

Diagnostic value of testosterone therapy in boys with delayed puberty [Kaplowitz] 116 (Ja)

Testosterone

Bone mineral status in hypopituitarism (letter) [Arisaka] 272 (Mr)

Diagnostic value of testosterone therapy in boys with delayed puberty [Kaplowitz] 116 (Ja)

Priapism following testosterone therapy for delayed puberty (letter) [Key] 1001 (Se)

Tetanus Toxoid

Pediatricians' recommendations for antipyretic agents with DTP immunizations: survey of current practice (letter) [Flanagan] 517 (My)

Poliovirus vaccine policy: another perspective [Katz] 1007 (Se)

Why wait for DTP-E-IPV? [Marcuse] 1006 (Se)

Tetracaine

Tack up warning on TAC (letter) [Mofenson] 519 (My)

Tetradecanoylphorbol Acetate

Increased phagocytic cell chemiluminescence in patients with cystic fibrosis [Roberts] 944 (Au)

Tetrahydrocannabinol

Short-term memory impairment in cannabis-dependent adolescents [Schwartz] 1214 (Oc)

Thalamus

Symmetrical thalamic degeneration with calcifications of infancy [DiMario] 1056 (Se)

Thalassemia

Acute changes in renal function associated with deferoxamine therapy [Koren] 1077 (Se)

Theophylline

Effects of theophylline on behavior and learning in children with asthma [Rappaport] 368 (Mr)

Prenatal cocaine exposure is associated with respiratory pattern abnormalities [Chasnoff] 583 (My)

Theophylline and school performance (letter) [Du Hamel] (reply) [Strunk] 1258 (No)

Thiamine Deficiency

Beriberi in Southeast Asian adolescent (letter) [Vrchota] 270 (Mr)

Thiamine Pyrophosphate

Beriberi in Southeast Asian adolescent (letter) [Vrchota] 270 (Mr)

Thigh

Hemangioma of thigh [Weisberg] 379 (Mr)

Thorax

Intrathoracic stomach with volvulus [Bonadio] 503 (Ap)

Umbilical cord circumference at birth (letter) [Patel] 638 (Je)

Thrombocytopenia

Hematologic syndrome of growth-retarded infants (letter) [Meberg] (reply) [Philip] 1260 (No)

Kawasaki disease with thrombocytosis followed by thrombocytopenia purpura in same patient (letter) [Lipnick] 139 (Fe)

Thrombocytosis

Kawasaki disease with thrombocytosis followed by

thrombocytopenia purpura in same patient (letter) [Lipnick] 139 (Fe)

Thrombosis

Plasma support for surgery in premature infant with factor IX deficiency (letter) [Pegelow] 639 (Je)

Thymus Gland

Ectrodactyly, ectodermal dysplasia, and clefting associated with thymic aplasia (letter) [Jhaveri] 12 (Ja)

Thyroid Diseases

Ultrasonic imaging in differential diagnosis of diffuse thyroid disorders in children [Ivarsson] 1369 (No)

Tin

Use of metalloporphyrins for chemoprevention of neonatal jaundice [Stevenson] 353 (Mr)

Tinea Capitis

Small, single-vertex lesion of scalp aplasia cutis congenita; *Trichophyton tonsurans*; aplasia cutis congenita [Cohen] 621 (My)

Tissue Culture

Diagnosis of group A, beta-hemolytic streptococcal pharyngitis in office setting: rapid latex test vs throat culture [Taubman] 102 (Ja)

Classified Advertising

All classified advertising orders, correspondence and payments should be directed to: American Journal of Diseases of Children, P. Box 1510, Clearwater, Florida 34617. Our telephone numbers are: National 800-237-9851; in Florida 800-553-8288; Local 813-443-7666. Please do not send classified ads, payments or related correspondence to the AMA headquarters in Chicago. This causes needless delay.

Inquiries about "BOX NUMBER" advertisements: All replies must be in writing and must cite the box number in the ad. Example: Box _____, c/o AJDC, P.O. Box 1510, Clearwater, Florida 34617. We are not permitted to divulge the identity of advertisers who wish the mail sent in care of American Journal of Diseases of Children.

CLASSIFIED INFORMATION

Regular Classified	1 Time	3 Times or more*
Cost per word	\$1.75	\$1.60
Minimum 20 words.		per issue

*In order to earn the three-time rate, your ad must be placed and prepaid at the same time for three or more issues.

Counting Words: Two initials are considered one word, each abbreviation is considered one word, and figures consisting of a dollar sign and five numerals or less are considered one word. Cities and states consisting of two words or more are counted as one word: i.e., "New York" and "Salt Lake City." Zip code is considered one word and must appear in all ads. Telephone number with area code is considered one word. When box numbers are used for replies, the words "Box _____, c/o AJDC" are to be counted as three words.

Classified Display	1 Time	3 Times
Full page	\$1,090	\$948
Two-thirds page	929	808
One-half page	763	664
One-third page	602	523
One-sixth page	278	242
Column inch	60	50

Minimum display ad: one column inch
12-time rate available on request.

Display Production Charge: The publication will pub-set advertisements upon request. The typesetting fee is 10% of the one-time ad cost shown above. Special requests will be billed to the advertiser and/or agency at the then prevailing rates.

Box Service

Available for all ads. The cost is \$10.00 for the first issue only. Responses to your ad will be consolidated in our office and promptly mailed directly to you.

Closing Date

The 25th of the second month prior to issue date. Example: The November issue closes September 25th. No ads can be cancelled after the closing date.

CARNATION®

GOOD NATURE™

Iron Fortified Follow-Up Formula

For babies over six months of age
eating solid foods

When baby reaches the solid food stage, approximately 6 months of age, formula is no longer his sole source of nutrition. Yet, whole milk* doesn't contain all the necessary vitamins and the high-carbohydrate cereals, fruits, and vegetables he eats are low in certain nutrients. And, older babies require less energy from fat¹ and more from protein.²

Carnation® GOOD NATURE™ Follow-Up Formula provides the added nutrients for the older baby's optimal growth and development. And it contains

more protein and calcium than starter formula to support the increased metabolic demands of bone mineralization and muscle mass growth.

The ratio of unsaturated to saturated fatty acids in GOOD NATURE is 2:1. GOOD NATURE is higher in monounsaturated fatty acids yet contains 28% less fat than starter formula to satisfy the changing needs of the older baby.

GOOD NATURE also has a carbohydrate blend of 63% corn syrup solids and 37% lactose to help assure tolerance. It contains 12 mg iron per quart to help ensure a sufficient supply at an age when inborn stores are depleted. GOOD NATURE costs less than starter formula and also tastes, smells, and looks like the real food baby is learning to enjoy.

When baby is ready for solid food, Mom may ask you about GOOD NATURE Follow-Up Formula. You can reassure her that GOOD NATURE is nutritionally sound and makes good sense for her baby.

For more information about GOOD NATURE Follow-Up Formula, please write to:
Carnation Nutritional Products,
5045 Wilshire Blvd., Los Angeles, CA 90036.

Carnation®
*Setting the stage
for better development™*

GOOD NATURE Follow-Up Formula...
now available to consumers in
32-fl-oz ready-to-feed fresh packs
and 12-oz easy-to-mix powder canisters.

"HOT"

Cool her fever with the brand that offers the most dosage choices

When your patients need fever relief, Children's **TYLENOL**® acetaminophen should be your first choice. **TYLENOL**® offers you more dosage choices than any other acetaminophen brand, so your patients get the right medicine in a form and flavor that's right for every child's needs:

- ☐ Alcohol-free Infants' Drops
- ☐ Alcohol-free Children's Elixir in Cherry and *New Grape* flavors
- ☐ Children's 80 mg Chewables in *both* Grape and Fruit flavors
- ☐ Easy-to-swallow 160 mg Junior Strength Coated Caplets for 6- to 14-year-olds

Remember, **TYLENOL**® is clinically proven as effective an antipyretic as aspirin, with a superior safety profile.^{1,2} And parents can easily find your recommendation, because **TYLENOL**® products are more widely available in food and drug stores than any other brand.³ So next time a little patient is "Hot!" with fever, make your first choice **TYLENOL**® acetaminophen.
